# THE LANCET.

A Journal of British and Foreign Medicine, Surgery, Obstetrics, Physiology, Chemistry, Pharmacology, Public Health, and News.

TELEGRAPHIC ADDRESS—LANCET, WESTRAND LONDON

TELEPHONE NUMBER—GERRARD 5356

NO. I. OF VOL. I., 1917.

No. 4871. Vol. CXCII.

LONDON, SATURDAY, JANUARY 6, 1917.

Price 8d.

By FREDERICK J. McCANN, M.D. Edin., F.R.C.S. Eng., Surgeon, Samaritan Free Hospital for Women, London, N.W.

## CANCER OF THE WOMB: ITS SYMPTOMS, DIAGNOSIS, PROGNOSIS, AND TREATMENT.

Fully illustrated. 20s. net.

LIVERPOOL MEDICO-CHIRURGICAL JOURNAL.—“Cancer of the Womb,” by F. J. McCann, is a book that can be recommended alike to the general practitioner and the specialist. Written in a fluent manner, it embodies the ripe experience of a renowned operator, trained observer, and patient investigator.”

DINBURGH MEDICAL JOURNAL.—“The book is one of very great merit; it will be read with interest both by the specialist and general practitioner as an authoritative exposition of the important subject with which it deals.”

PRACTITIONER.—“Dr. McCann has produced a valuable work which deserves to be widely known.”

ST. BARTHOLOMEW'S HOSPITAL JOURNAL.—“The plates are excellent. This is a book we can thoroughly recommend.”

London : Henry Frowde and Hodder & Stoughton.

SECOND EDITION. Pp. xiv. + 498. With 79 Illustrations. Plain and Coloured. Price 10s. 6d. net.

## MACEWEN'S SURGICAL ANATOMY.

“The book is a good one and should prove useful to students and practitioners alike.”—LANCET.

London : Baillière, Tindall & Cox, 8, Henrietta-street, Covent Garden.

## THE PRESCRIBER'S COMPANION FOR 1917.

Price 15s. net.

Post free 15s. 7d.

## SQUIRE'S COMPANION to the BRITISH PHARMACOPÆIA.

An Epitome of over Half a Century's progress in

THERAPEUTICS, CHEMISTRY, and PHARMACUTICS.

Published by J. & A. Churchill, 7, Great Marlborough-street, W.

See also page 15.

## BY SIR WILLIAM BENNETT, K.C.V.O., F.R.C.S.

Crown 8vo. 5s. net.

## INJURIES AND DISEASES OF THE KNEE JOINT.

With 34 Illustrations.

Nisbet & Co.

Also

8vo. 6s. FOURTH EDITION.

## MASSAGE AND MOVEMENTS IN RECENT FRACTURES; SPRAINS AND THEIR CONSEQUENCES; RIGIDITY OF THE SPINE AND THE MANAGEMENT OF STIFF JOINTS.

With 23 Illustrations.

Longmans, Green & Co.

Now Ready. Crown octavo. 56 pp. Illus. Price 1s. net; by post 1s. 2d.

## NOTES ON MILITARY ORTHOPÆDICS.

By PAUL BERNARD ROTHE, F.R.C.S. “Should be in the hands of every surgeon on active service.”—MEDICAL WORLD.

Henry Kimpton, 283, High Holborn, London, W.C.

Now Ready. Pp. xi. + 289. With 3 Charts. 5s. net.

## ON ALCOHOLISM: Its Clinical Aspects and Treatment.

By FRANCIS HARE, M.D., Medical Superintendent of the NORWOOD SANATORIUM, Beckenham.

“Marked by candour, common sense, and moderation ..... likely to become the standard text-book.”—BRITISH MEDICAL JOURNAL.

London : J. & A. Churchill, 7, Great Marlborough-street.

## BY FRANK KIDD, F.R.C.S., Assistant Surgeon at the London Hospital and Surgeon-in-Charge of Genito-Urinary Department, London Hospital.

In the Press, to be published shortly.

## COMMON DISEASES OF THE MALE URETHRA

Being a Course of Lectures delivered at the London Hospital, designed to assist those who may be starting Genito-Urinary Clinics.

BY THE SAME AUTHOR. Price 7s. 6d. net.

## URINARY SURGERY. A REVIEW.

“This book can be thoroughly recommended to those who are desirous of being acquainted with the modern position of Urinary Surgery.”—GLASGOW MEDICAL JOURNAL.

London : Longmans, Green & Co., 39, Paternoster-row, E.C.

No. 4871.]

THE LANCET is registered as a Newspaper. All rights reserved.

[FOUNDED 1823.

ON DISEASES of the LUNGS and PLEURÆ, including TUBERCULOSIS and MEDIASTINAL GROWTHS.

By Sir RICHARD DOUGLAS POWELL, Bart., K.C.V.O., M.D. Lond., F.R.C.P., and P. HORTON SMITH HARTLEY, C.V.O., M.D. Camb., F.R.C.P.

Fifth Edition.

With 29 Plates (six coloured) from Original Drawings, and 53 Illustrations in the text. Demy 8vo. 2ls. net; inland postage, 1d., abroad, 1s. 4d.

“We can safely say that no affection of the lungs has escaped the notice of the writers.”—THE LANCET.

London : H. K. Lewis & Co. Ltd., 136 Gower-street, W.C.

Demy 8vo. 3s. net; post free, 3s. 4d.

## A NEW TREATMENT FOR GONORRHOEA.

By CHARLES RUSS, M.B., M.R.C.S., L.R.C.P., Physician-in-Charge, Electro-Therapeutic Department, Male Lock Hospital, London.

[Now Ready.

“This form of treatment merits further attention, as it is both scientific and ingenious. Instead of attacking the gonococci in their strongholds by means of bactericidal agents, which too often do not reach them, they are lured, so to speak, from their entrenchments by electrolytic action.”—BRITISH MEDICAL JOURNAL.

London : H. K. Lewis & Co. Ltd., 136 Gower-street, W.C.

## SAUNDERS' BOOKS

FOR THE PRACTITIONER.

See Saunders' Advertisement on Page 5.

Second Edition, Enlarged. Now Ready. Crown 8vo. 6s. net. With 30 original Photographs and 150 special Prescriptions.

## TREATMENT OF DISEASES OF THE SKIN.

By KNOWSBY SIBLY, M.D. Camb., Physician to St. John's Hospital for Diseases of the Skin.

“The most recent methods of treatment, CO<sub>2</sub>, hyperæmia, X rays, electrolysis, ionisation, high-frequency ..... are explained. It will be of the greatest value to the general practitioner, and we can thoroughly recommend it.”—PRACTITIONER.

London : Edward Arnold, 41 and 43, Maddox-street, W.

## OPERATIVE TREATMENT OF FRACTURES.

By Sir ARBUTHNOT LANE, Bart., M.S.

SECOND EDITION.

With 226 Illustrations. 10s.

The Medical Publishing Company, Ltd., 23, Bartholomew Close, E.C.

## THE PRACTISHER.

The Journal that keeps you posted.

10s. per annum, 20s. for three years, post free.

WRIT & FOR SPECIMEN COPY.

Offices : 6, South Charlotte-street, Edinburgh.

FOURTH EDITION. JUST PUBLISHED.

8vo. Pp. 260. With 40 Illustrations. Cloth. 6s. net.

## SQUINT: its Causes, Pathology and Treatment.

By CLAUD WORTH, F.R.C.S.

Surgeon, Royal London Ophthalmic Hospital (Moorfields), &c.

Bale, Sons & Danielson, 83, Gt. Titchfield-street, W.

Pp. iv. + 64. Price 3s. 6d. net.

## INTENSIVE TREATMENT OF SYPHILIS AND LOCOMOTOR ATAXIA BY AACHEN METHODS.

By REGINALD HAYES, M.R.C.S.

THE LANCET says:—“No better exposition of the method as practised at Aachen can be found than that contained in this little work.”

London : Baillière, Tindall & Cox, 8, Henrietta-street, Covent Garden.

# THE THROAT THE GERM AND THE LOZENGE

The warm moist condition of the throat being so favourable for the growth of Bacteria is a source of constant trouble to the Doctor.

He is constantly being asked, "Oh give me something to ease my throat."

Diet and treatment are necessary, but take time.

For immediate relief try "**COFECTANT**" **LOZENGES**, they are pleasant to the taste; they contain "**COFECTANT**," the most powerful germicidal fluid known; they are harmless and they kill germs, thereby relieving the hoarseness and soreness immediately, and leaving the Doctor to restore the patient to health in his own way and with greater comfort to both.

*1/3 Per Box from all High-class Chemists.*

**EDWARD COOK & CO., LTD.,**  
**Bow, LONDON, E.**

# THE LANCET.

No. 4871.

LONDON, SATURDAY, JANUARY 6, 1917.

Vol. CXCII.

## CONTENTS.

*The whole of the literary matter in THE LANCET is copyright.*

A LECTURE on the Conditions which Govern the Growth of the Bacillus of "Gas Gangrene" in Artificial Culture Media, in the Blood Fluids *in vitro*, and in the Dead and Living Organism. Delivered before the Royal Society of Medicine on Dec. 18th, 1916, by Colonel Sir ALBRECHT H. WRIGHT, C.B., M.D., F.R.S., a Consultant Physician to the British Army in France. (Illustrated) 1

### ORIGINAL ARTICLES.

Orthopaedic Methods in Military Surgery. By D. McCRAE AITKEN, M.B., Ch.B. Edin., F.R.C.S.—(Illustrated) 10

Report on Six Cases of *Amara Histolytica* Carriers Treated with Emetine Bismuthous Iodide. By Captain O. G. INSBIE, C.A.M.C., and Lieutenant W. ROCHE, R.A.M.C. (Report to the Medical Research Committee.) 17

Surface-Tension and the Wassermann Reaction. By VINCENT B. NESFIELD, F.R.C.S. Eng., &c., Major, Indian Medical Service 18

### CLINICAL NOTES:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

Notes on a Case of Traumatic Hernia of the Diaphragm Proving Fatal Seven Months after the Wound. By C. P. SYMONDS, M.R.C.P. Lond., Temporary Captain, Royal Army Medical Corps.—(Illustrated) 18

A Note on the Blood Changes in Gas Poisoning. By JAMES MILLER, M.D. Edin., F.R.C.P. Edin., Captain, Royal Army Medical Corps (T.); and HARRY RAINY, M.A., M.D. Edin., Captain Royal Army Medical Corps (T.) 19

### REVIEWS AND NOTICES OF BOOKS.

Medical Diseases of the War. By Arthur F. Hurst, M.A., M.D. Oxon., F.R.C.P. Lond., Temporary Major, R.A.M.C. 20  
The Treatment of Infantile Paralysis. By Robert W. Lovett, M.D. 21  
Medical and Veterinary Entomology. By William B. Herms 21  
Paton's List of Schools and Tutors, 1917 21  
The Passing on of Life: A Talk about Ourselves. By the Viscountess Falmouth 21  
The Greek Tradition: Essays in the Reconstruction of Ancient Thought. By J. A. K. Thomson, M.A. 21  
Miscellaneous Volumes 21

### REPORTS AND ANALYTICAL RECORDS FROM THE LANCET LABORATORY.

Eucalyptol (Cineol) 22  
"Small Tea" 22  
"Solid" Naso-pharyngeal (Buccaine) Compound 22  
"Dial-Ciba" 22

### LEADING ARTICLES.

AN IDEAL FOR THE NEW YEAR. 23  
THE LIQUOR TRAFFIC AND THE FOOD QUESTION. 23  
WELFARE WORK IN FACTORIES. 25

### ANNOTATIONS.

The Government Laboratory and the War 26  
Staphylococcal Meningitis 26  
The Metropolitan Water-supply 26  
Anesthesia in America 27  
Experimental Attempts to Transmit Pellagra 27  
Uveoparotid Fever 28  
The Tercentenary of Bartholin. 28  
THE LANCET, VOL. II., 1916: Index Notice 28

### SPECIAL ARTICLES.

Dentifrices 29  
The Control of Venereal Diseases: Scheme for the City of London.—Early Experience of Statistical Notification in Western Australia.—Routine Treatment of Venereal Diseases.—Treatment of Pregnant Women. 30  
Canada: Canadian Research Board.—Pension and Discharge Boards.—The Tuberculous Soldier in Canada.—The Clayton Convalescent Home, Halifax, N.S.—Infantile Paralysis in Ontario.—The Problem of the Feeble-minded in Toronto. 30  
Paris: Infant Welfare in Paris during the Second Year of War.—The Excellent Sanitary State of Paris.—Treatment of Gunshot Wounds with Ointments.—Antisypilistic Measures in Morocco.—The Action of Picric Acid on Blue Fus. 31  
The Services 33

### VITAL STATISTICS:

Health of English Towns 32  
Health of Scotch Towns 32  
Health of Irish Towns 33

### CORRESPONDENCE.

The Nomenclature of "Internal Secretion" (Dr. W. Blair Bell) 33  
The Parliamentary Representative of Dublin University (Prof. A. Francis Dixon, Prof. James Craig) 33  
"Shell Shock" (Dr. Thomas Lumadene) 34  
Lord Roberts's Field Glasses: A Retrospect of Two Years' Work (Lady Roberts) 34  
The Results of Feeding Mice with Mouse Cancer (Prof. A. S. Leyton, Dr. H. G. Leyton) 34  
Suprarenal Hemorrhage in Cerebro spinal Fever (Lieut. S. G. Scott, R.A.M.C.) 34  
Milk in the Diet of Infants (Dr. Douglas Firth) 41  
Pilewort (Mr. Fredk. W. Alexander) 41  
The Question of Prohibition (Mr. H. N. Robson) 42  
Irish Nurses and the College of Nursing, Limited 42

### THE WAR.

The Casualty List 37  
The Honours List 37  
Mentioned in Despatches 38  
The Somme Campaign 38  
Deaths among the Sons of Medical Men 39  
Canadian Army Medical Service 39

**JOHN BALE, SONS & DANIELSSON, LTD.,**  
PRINTERS, PUBLISHERS, & PROCESS BLOCK MAKERS.

**A LECTURE ON MEANS FOR THE PROLONGATION OF LIFE.**

By SIR HERMANN WEBER, M.D., F.R.C.P. 4th Edition, demy 8vo, pp. 248. Cloth, 4s. 6d. net; postage 4d.

"It is an eminently sane, scientific, and common-sense volume, and we know of no book which is so helpful a practical guide to the preservation of health in later life, and to the promotion of a kindly and efficient old age."—*Polycyclic.*

"We can strongly recommend this most agreeably written book to all practitioners who wish to be able to give sound advice to their elderly patients."—*Medical World.*

" Himself a living example of the possibility of maintaining sound health into the ninth decade, Sir Hermann Weber is able to place these various considerations in their true perspective."—*British Medical Journal.*

## JOHN BALE, SONS & DANIELSSON, LTD.

PRINTERS, PUBLISHERS, & PROCESS BLOCK MAKERS.

### DEFECTIVE CHILDREN. A Work for School Medical Officers and all Medico-Educationists.

Edited by T. N. KELYNACK, M.D. 7s. 6d.; postage 6d.

"It contains so much of value to the physician that we expect a second and enlarged edition may soon be required."—*The Practitioner*. "Each of the sections has been written by a contributor possessing first-hand knowledge, and the editor has been fortunate in the collaborators.... The book has been carefully schemed, and its component parts have been admirably executed; it is probably unique in its utility and its freedom from undigested platitudinous vapourings."—*The Polyclinic*.

"Dr. Kelynack's book should certainly be read in connection with the Board of Education's Medical Report. It is a collection of the writings of experts."—*The Journal of Education*.

### THE CHILD WELFARE ANNUAL. An indispensable Book of Reference. 7s. 6d. net; postage 6d.

"..... deals with the practical means taken to achieve the patriotic purposes of rearing an imperial race."—*Lady's Pictorial*.

### TUBERCULOSIS IN CHILDREN. By Prof. G. CORNET. Roy. 8vo. 527 pp. 15s. net; postage 6d.

"The whole volume is full of interest."—*Lancet*.

"A vast amount of information is conveyed in plain terms, indicating the bad as well as the good points of most of the accepted methods."—*British Medical Journal*.

83, 85, 87, 89 & 91, GREAT TITCHFIELD ST., OXFORD ST., LONDON, W.

**JOHN BALE, SONS & DANIELSSON, LTD.,**  
PRINTERS, PUBLISHERS, & PROCESS BLOCK MAKERS.

EVERYONE who desires to be kept in touch with all that is happening in regard to Maternity and Child Welfare should  
subscribe at once to the New Publication

**MATERNITY AND CHILD WELFARE.**

MONTHLY, 6d. net.

PER ANNUM, 6s. Post Free.

A Journal conducted in the sole interests of the Mother and the Child—in particular the young child short of school age—and edited by a  
Medical Man with the co-operation of representatives of workers in intimate association with the aims and needs of the various Centres  
throughout the United Kingdom.

The Publishers appeal to Medical Officers of Health and others to make the Journal known amongst workers with whom they come in contact.

83, 85, 87, 89 & 91, GREAT TITFIELD ST., OXFORD ST., LONDON, W.

A Lecture

ON THE

CONDITIONS WHICH GOVERN THE GROWTH  
OF THE BACILLUS OF "GAS GANGRENE"  
IN ARTIFICIAL CULTURE MEDIA,  
IN THE BLOOD FLUIDS *IN VITRO*, AND IN THE  
DEAD AND LIVING ORGANISM.

*Delivered before the Royal Society of Medicine on  
Dec. 18th, 1916,*

BY COLONEL SIR ALMROTH E. WRIGHT,  
C.B., M.D., F.R.S.,

A CONSULTANT PHYSICIAN TO THE BRITISH ARMY IN FRANCE.

My subject-matter to-day is not, as on previous occasions, the general question of the treatment of infected wounds. It is a much narrower issue. I would propose to consider with you the conditions which respectively promote and inhibit the growth of the "gas gangrene" bacillus of Welch, but here also I shall have in view a purely practical end. The investigation of the conditions which favour or hinder the growth of the organism here in view has, as I see it, only one possible object. That is to conduct sooner or later to the saving of life and limb.

I may, I think, take it as certain that clinical observation is incompetent to furnish us with any precise information regarding the conditions with favour or impede the growth of the bacillus of gas gangrene, and that such information can be obtained only by laboratory investigation. But that does not mean—and we must never lose sight of this—that we can place unrestricted confidence in inferences based upon laboratory experiments. For in laboratory experiments we make for ourselves artificially simplified conditions; and confine our attention to a very limited number of factors. By virtue of this we are subject to make erroneous generalisations, concluding that what holds true under the conditions obtaining in the laboratory experiment will hold true universally. Presumptions of that kind can be avoided only by continually extending and critically revising our laboratory experiments and organising inquiries to find out whether our doctrines really give good results in practice.

And it is specially necessary to take these precautions when therapeutic procedures are based upon laboratory data. For quite a large proportion of such therapeutic procedures rest either upon generalisations which do not apply outside the conditions which are obtained in the experiments, or else upon generalisations which emphasise the thing that is unimportant to the prejudice of the thing that is important. I have in my mind, for example: the doctrine that antiseptics will sterilise an infected wound; and, in connexion with my present subject-matter, the doctrine that the growth of the gas-gangrene bacillus pivots upon the presence or absence of oxygen. It will provide me with a convenient point of departure to invite you to consider what is the experimental basis of this doctrine.

I. CONDITIONS WHICH GOVERN THE GROWTH OF THE  
BACILLUS OF WELCH IN ARTIFICIAL MEDIA.

To practically all of us the most important scientific datum ascertained with regard to the bacillus of Welch is that it will not grow in the presence of air. And this datum, firmly believed, has dominated all surgical thinking in the domain of gas gangrene. It has led to the employment of oxygen or peroxide of hydrogen injected into the tissues as a sovereign remedy against the progress of gangrene. And it has suggested that the advantage of thoroughly opening up a wound infected by anaerobes is, in the main, advantage derived from letting in the air.

But the thesis upon which all this rests—the thesis that the bacillus of Welch cannot grow and multiply in a presence of air—is as a matter of fact erroneous. It was discovered by Tarozzi that when pieces of animal tissue were added to bouillon cultures of anaerobes could be obtained in open tubes. Ori and Wrzosek, following up this work, showed that the same result could be obtained with pieces of either raw or autoclaved potato, and also with other vegetable tissues. Nor are these, as might be supposed from the fact that we have continued to think along the old

lines, very recent discoveries; nor, again, do the aerobic cultures of anaerobes here in question yield only meagre growth. Quite the contrary. The work of Ori and Wrzosek dates back already some ten years. And in reality the cultures of the bacillus of Welch grown in the open in bouillon containing a piece of potato are characterised by very rapid and vigorous growth, with gas production. So vigorous in point of fact is the growth of the bacillus of Welch in the open potato bouillon tube, that this method furnishes, it would seem, the best method for isolating the microbe from specimens of pus in those cases where the organism is present in only very small numbers.

There are displayed before you here a series of open culture tubes implanted with the bacillus of Welch, all showing by their turbidity and by foaming how vigorous is the growth. And, in order that the erroneous mental images which the appellation "anaerobes" nurtures in the mind may be obliterated, I have ranged up before you here also cultures in open of a variety of other anaerobes. And let me say that so far we have not obtained any anaerobe from a wound which cannot by proper devices be made to grow freely in open tubes.

You can see that it follows from this, that we cannot possibly promise ourselves that if we introduce oxygen into the tissues, or admit air to the interior of the wound cavity, we shall thereby inevitably arrest a gangrene bacillus infection. Or, putting the conclusion in more general form, we see that the therapeutic principle of combating anaerobes by combating anaerobic conditions cannot be regarded in any sense as an adequate therapeutic principle.

Let us be careful to read the lesson of these tubes aright. All that they teach is that anaerobic microbes can be got to grow with astonishing freedom in culture tubes fully open to the air. But it is not thereby established that the presence of oxygen is either indifferent or congenial to anaerobic microbes. And, in point of fact, it has been suggested, and the view is *a priori* tenable, that the potato may provide some reducing agent which by holding off the oxygen of the air at the outset enables the microbes to get a start, the subsequent growth being due to anaerobic growth in a medium deprived of air by the generation of gas in the culture. This hypothesis that the potato furnishes a reducing substance which gives the culture a start seems to win support from the fact that the potato bouillon gives much less vigorous cultures when stale than when freshly prepared. And, again, the traditional view that oxygen is inimical, or at least uncongenial, to the growth of the class of microbes denoted "anaerobes" does not entirely lack support. When after implanting I empty out the major part of the contents of a potato bouillon tube, reserving only a few c.c.'s, and then lay the tube on its side in the incubator, I get only a very meagre culture. The same holds true when I draw a continuous stream of air bubbles through the culture, and again in the case when cultivating in a capillary tube, I break up my column of fluid by intercalating a number of air bubbles. Moreover, when I endeavour to subculture from the meagre cultures of anaerobes grown under such conditions of maximum exposure to air, I am practically always unsuccessful. But all these considerations do not avail to obscure the fact that we are required to abandon the traditional view that the growth of anaerobes pivots upon the presence or absence of oxygen. And after taking cognisance of these cultures in open tubes we are intellectually impoverished to the extent that we see that the doctrine of anaerobic growth that, as we thought, held unrestrictedly, holds true only with limitations.

Intellectual impoverishment is, however, impetus to research. And now that the presence or absence of oxygen turns out not to be the factor which controls the growth of the bacillus of Welch, there is stimulus to try to find out what is the controlling factor, or rather what are the controlling factors. For—it being in the order of nature that things should never be too easy—there are bound to be many controlling factors. I and my fellow workers, Major Georges Dreyer at Boulogne and Dr. Alexander Fleming at St. Mary's, have consequently set ourselves to search for these controlling factors. In each case we set out to look for mechanical factors which might favour or hinder the growth of the bacillus of Welch.

The first question to which investigation was directed was the question as to what would be the effect of in the one case dispersing the implanted microbes through the culture

medium, and in the other case concentrating the infection in some one region of the culture medium. I had already 17 years ago, in a study\* of the distribution of agglutinins and bactericidal substances in the body in cases of typhoid and Malta fever, called attention to the circumstance that microbes which would if carried into the blood stream have been killed or impeded in their growth by the bacteriotoxic powers of the blood succeeded in maintaining themselves alive in the internal organs, collected together in what I called "niduses of lowered bacteriotoxic pressure"—i.e., in regions where because collected together they can by active and passive chemical force maintain conditions propitious to their survival. In view of this analogy, and in view also of the circumstance that for the successful starting of a culture of the bacillus of Welch a large implantation is usually required, it appeared not unreasonable to inquire from experiment whether concentration of the infection comes into account also in connexion with growth upon artificial media.

The experiments were in each case carried out with measured volumes of glucose broth implanted with graduated additions of a suspension of Welch's bacillus, and cultivated anaerobically in capsules of glass tubing or capillary pipettes. In each case duplicate volumes were taken, and the one tube was cultivated lying flat and the other in the upright position—the microbes in this latter being concentrated at the bottom either by gravitation or centrifugation. In every series of such experiments—and in all eight were performed—the advantage from the point of view of successful cultivation of the microbe was with the series of tubes that were incubated in the upright position. The following may serve as an illustrative experiment.

#### Experiment 1.

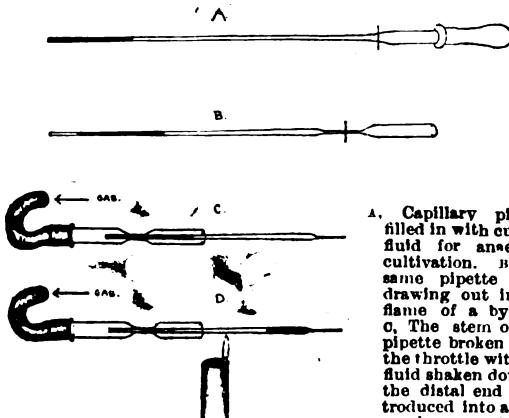

A 24 hours culture of the bacillus of Welch, grown upon serum agar<sup>1</sup> in an atmosphere of coal-gas sealed up in a test-tube drawn out in the blow-pipe flame, was suspended in a convenient quantity of glucose broth. This suspension, enumerated in a Thoma-Zeiss cell, was found to contain 220,000,000 microbes (the actual figure arrived at was 217,600,000). From this a graduated series of dilutions were made in glucose broth. Two 20 c.mm. volumes of each dilution were then taken up into graduated capillary pipettes and anaerobic conditions were provided by driving the column of fluid down to the throttled distal end of the tube and then sealing up the proximal end filled with coal-gas.<sup>2</sup>

\* THE LANCET, 1899, II, 1727.

<sup>1</sup> Serum or blood agar—i.e., agar which has been flushed with a very minute quantity (10 c.mm. is enough) of blood or serum—furnishes, in my experience, a very much more satisfactory culture medium for the bacillus of Welch than ordinary agar. Not only does it give a more abundant culture but we obtain a much larger proportion (in the present experiment 100 per cent.) of living microbes. That ordinary agar provides in many instances a comparatively unfavourable culture medium would seem to be deducible also from Miss Robertson's careful work. For her result—the result that colonies of the bacillus of Welch contain even after repeated platings an admixture of other anaerobic microbes—would seem to me to indicate that her medium grew the bacillus of Welch very badly in pure culture and satisfactorily only when admixed with other anaerobes which functioned as foster-nurses.

<sup>2</sup> The most convenient method of culture for experiments such as this is the "gas-piston" method illustrated in the accompanying figure.

FIG. 1.

d. After the fluid has been driven down to the distal end of the pipette by the piston action of the gas the tube is sealed up at the tip, and then in its middle in the flame of a by-pass.

The cultural results are here set out in tabular form.

#### Experiment 1.

Serial number of the dilution.	Number of microbes in 20 c.mm. of that dilution.	Cultural result in the tube standing upright.		Cultural result in the tube lying flat.	
		After 24 hours.	After 48 hours.	After 24 hours.	After 48 hours.
1	400,000	Growth	Growth	Growth	Growth
2	80,000	Growth	Growth	Growth	Growth
3	16,000	Growth	Growth	Growth	Growth
4	3,200	Growth	Growth	Growth	Growth
5	640	Growth	Growth	0	Growth
6	128	Growth	Growth	0	Growth
7	25	Growth	Growth	0	Growth
8	5	0	Growth	0	0
9	1	0	Growth	0	0

An effect essentially similar to that produced by collecting the infection into a restricted region of the cultural fluid ought, as reflection will show, to be achievable also by dividing up the culture medium by a series of partitions. For the chemical effort which the microbes will have to put forth for the transformation of the provided culture medium into a really propitious medium will, when that is divided up, be concentrated upon a fraction of the whole.

The experiment, conducted in duplicate, set out in the table below seems to indicate that this does hold true.

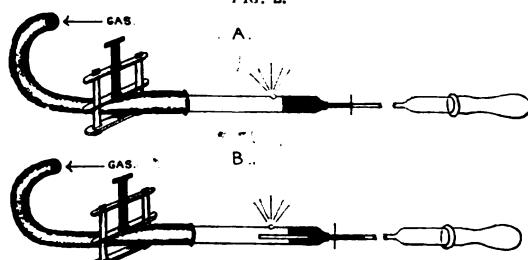

#### Experiment 2.

Serial number of the dilution.	Number of microbes in each 100 c.mm. of the dilution.	Volume of dilution taken for anaerobic culture in tubes lying flat.			
		100 c.mm. as a single unit.		100 c.mm. divided up by gas <sup>3</sup> into five units of 20 c.mm.	
		A.	B.	A.	B.
1	102,400	+	0	+++ + 0	++++ + 0
2	20,480	+	+	+ 0 0 0 0	+ + 0 0 0
3	4,096	+	+	0 + 0 0 0	+ + + 0 0
4	820	+	0	+ + + + 0	0 0 0 0 0
5	165	+	+	0 + 0 0 0	+ + 0 0 0
6	36	+	+	+ + + 0 0	+ 0 0 0 0
7	7	+	0	0 + + 0 0	+ + 0 0 0

Other and more interesting experiments falling entirely into line with those which have been in question above are the experiments devised and carried out by Dr. Alexander Fleming. You have these cultural experiments in open tubes displayed for view here. We have, first, a culture of the bacillus of Welch obtained by introducing a pledget of asbestos into glucose broth left open to the air; secondly, a culture obtained under the same conditions with a pledget of cotton-wool; thirdly, a culture obtained by the addition of platinum black; fourthly, one obtained with a rust-covered nail; and fifthly, a culture obtained by introducing into the open bouillon a hair-fine capillary glass tube filled in with a minute quantum of a diluted culture. When we take cognisance of all these—and you see we have here in each case a turbid and vigorous gas-producing culture—and when we bring what we see here into relation with the fact that we obtain cultures also in open tubes containing potato,

<sup>3</sup> The dividing up of the column of fluid by bubbles of gas was carried out by the technique depicted in the subjoined figure.

FIG. 2.

Method of filling into the stem of a capillary pipette a series of unit volumes of culture fluid separated by bubbles of gas. A. Showing method of filling in the first unit volume of culture fluid. B. Fiduciary mark on distal portion of the stem of capillary pipette. B. Showing method of filling in gas to partition off the successive unit volumes of culture fluid.

carrot, white haricot beans, bread, cabbage, cheese, earth, desiccated and ground-up albumin, and other additions, it comes home to us that the common factor here must almost certainly be a mechanical factor. And that mechanical factor would appear to be the providing of some hole or cranny to serve as a nidus in which the microbe can get a start by concentrating its chemical effort at first upon a fractional portion of the provided culture medium. Again, when we look beyond these test-tube experiments to clinical facts we see that the supervention of gangrene is very frequently correlated with the leaving behind in the wound of infected portions of clothing; we see, in other words, that the same mechanical factor which is operative in the test-tube experiment would seem to come into account also in the body.

## II. CONDITIONS WHICH GOVERN THE GROWTH OF THE BACILLUS OF WELCH IN THE BLOOD-FLUIDS.

### (a) Bactericidal Factor.

In the matter of the culture of the bacillus of Welch in the blood-fluids the factor which more than any other factor comes into account is—and this was shown by Captain d'Este Emery when he was my fellow worker at Boulogne—the bactericidal action of the serum. The following experiment shows how considerable is this restraining and bactericidal action of the normal serum. It brings out also the fact that the implanted microbes have a better chance of surviving and establishing themselves when collected together than when dispersed through the blood fluids.

### Experiment 3.

This experiment was a companion experiment to Experiment 1 (*supra*), and is to be read in connexion with it. The same bacterial suspension was employed and the procedure was, except in the respect that the dilutions were made in the author's serum instead of in glucose broth, the same.

#### Experiment 3 (Companion to Experiment 1).

Serial number of the dilution.	Number of microbes in 20 c.m.m. of that dilution.	Cultural result in the tube incubated upright.	Cultural result in the tube incubated lying flat.
1	400,000	Growth	Growth
2	80,000	Growth	0
3	16,000	0	0
4	3,200	0	0
5	640	0	0
6	128	0	0
7	25	0	0
8	5	0	0
9	1	0	0

We see here (computing from the figures for the tubes lying flat, i.e., the tube in which the microbes were dispersed through the culture medium) that 1 c.c. of normal serum was capable of disposing of an implantation of 4,000,000 ( $80,000 \times 50$ ) gas gangrene bacilli, all of which bacilli were (as the control experiment, Experiment 1, shows) living bacilli.

### (b) Mechanical Factor.

Also we can see here that advantage accrues to the blood-fluids when the microbes are dispersed and cannot coöperate, and disadvantage when the microbes are collected together and afforded an opportunity of making a combined attack. The influence of this factor of dispersing or concentrating the infection comes out more clearly when we make similar implantations into duplicate volumes of serum, we centrifuge the tube containing the one portion and incubate it upright, and leave the other tube uncentrifuged and incubate it lying flat.

In the following experiments the cultures were made anaerobically by the "gas-piston" method. The implantations were in Experiments 4 and 5 made by the "method of

It comes out, as you will see, quite clearly in these experiments that the doctrine of the "non-bacteriotropic nidus"—which I suggested to explain the survival of microbes in an organism which has in its blood stream an ample provision of protective substances—is a doctrine which applies also to cultivations in serum conducted *in vitro*. And the full details of the experiments, if there were room to give them here, would bring out that the more rapidly the concentration of the implanted microbes is effected, and the shorter the preliminary exposure to the full bactericidal action of the serum, and again the less bactericidally potent the serum, the greater becomes the chance that an implanted microbe will get a start and go on from that to produce a generalised infection.

Up to this point the problem of the conditions which govern the growth of the bacillus of Welch in the blood-fluids has been treated as if practically all that was of moment was to withdraw by mechanical methods the implanted microbes from full exposure to bactericidal power of blood-fluids. But even here the factor which is in ultimate analysis the operative factor is, of course, the chemical factor. What comes into account is, on the one hand, the diminished mass effect exerted by the bacteriotropic action of the serum upon the microbes; and, on the other hand, the increased mass effect exerted upon the phylactic elements of the blood-fluids by the products elaborated by the chemical activity of the microbes.

When the bacillus of Welch grows freely in serum it reduces the antityptic power of the medium and it elaborates acid. Concurrently, as it would seem with this, the microbe starts to grow with phenomenal rapidity after the manner of an avalanche gathering force as it goes. Our next task must be to inquire whether there is any causal relation between the reduction of antityptic power and the avalanche-like progression of the culture.

(o) *Experiments showing that the Culture of the Bacillus of Welch in Serum is Largely Governed by the Antityptic Power of the Blood.*

The question as to what it is that converts the pus of neglected wounds into an ideally propitious culture medium for the gangrene bacillus and every other species of microbe presented itself very early in the course of this war. To that question I proposed an answer, and I think with every day it has become clearer that it was the right answer. That answer was to the effect that what stands in the way of free growth of all micro-organisms in the blood-fluids is the antityptic power. We have to suppose in connexion with this that the antityptic power inhibits the digestive processes which must precede the conversion of the native albumins of the blood into congenital pabulum for

microbes. It therefore seemed to follow that if trypsin were directly added to the blood-fluids, or else if trypsin were indirectly added, and this is what occurs in stagnant pus by the disintegration of the leucocytes, we should have a corruption of the discharges, every manner of microbe cultivating itself there without restraint. In brief, what I suggested was that the antitryptic power is the guardian of the blood. In connexion with this I would point to the experiments of my fellow workers, Captains S. R. Douglas and L. Colebrook. They have shown that haemocultures, otherwise so frequently infertile, can very often be rendered fertile by the addition of trypsin to the culture medium. And the following experiments, conducted with the bacillus of Welch, show exactly the same thing.

#### Experiment 7.

A 24 hours culture of the bacillus of Welch grown upon agar flushed with serum was suspended in a convenient quantum of glucose broth. This was found to contain 350 millions of bacilli per c.c. Graduated dilutions of the suspension were then made in a serum (A. E. W.'s) which neutralised an equal bulk of a 25-fold dilution of trypsin. Another precisely similar series of dilutions was made in another sample of the same serum to which had been added 1/25th of its bulk of the same sterile trypsin undiluted. Six 20 c.m.m. volumes of each successive dilution of either serum were then taken up into calibrated capillary pipettes for anaerobic cultivation. The cultural results as determined by microscopic examination were as set out below.

Serial number of the dilution.	Number of microbes in the 20 c.m.m. volume which was cultivated.	Unaltered serum.		Trypsinised serum.	
		Number of fertile cultures.		Number of fertile cultures.	
		Number of	fertile cultures.	Number of	fertile cultures.
1	7,000,000	6	out of 6	6	out of 6
2	1,400,000	5	" 6	6	" 6
3	280,000	0	" 6	6	" 6
4	56,000	0	" 6	5	" 6
5	11,200	0	" 6	2	" 6
6	2,240	0	" 6	0	" 6
7	450	0	" 6	0	" 6
8	90	0	" 6	0	" 6
9	18	0	" 6	0	" 6

We see here that for the infection of 20 c.m.m. of trypsinised serum there were required 50 times fewer microbes (33,600 as contrasted with 1,700,000) than for the infection of the same quantity of unaltered serum.

#### Experiment 8.

Here in the one set of tubes a wash of trypsin followed by a wash, or fraction of a wash, of the bacillus of Welch were added to serum; in the control tubes larger quanta of microbial culture were implanted.

Control tubes	Serum + 3 washes of bacterial suspension.	No growth.
	" + 2 "	" "
	" + 1 wash "	" "
	" + ½ "	" "
Trypsin tubes	Serum + 1 wash trypsin, 1 wash bacterial suspension.	Abundant growth with gas.
	" + 1 wash trypsin, ¼ wash bacterial suspension.	"

#### Experiment 9.

Here the same procedure was followed.

Control tubes containing normal serum	Serum + 4 washes of bacterial suspension.	No growth.
	" + 3 "	" "
	" + 2 "	" "
	" + 1 wash "	" "
	" + ½ "	" "
Tubes containing trypsinised serum	" + 2 washes "	Abundant growth with gas.
	" + 1 wash "	" "
	" + ½ "	" "
" + ¼ "	" "	"

#### Experiment 10.

Here again the same technique was employed except in the respect that the trypsinised serum was prepared by adding 1 unit volume of trypsin respectively to 9, 19, and 39 unit volumes of serum. The serum was A. E. W.'s serum,

which neutralised an equal volume of a 25-fold dilution of trypsin. The cultural results were as set out below.

		Amount of bacterial suspension implanted.					
		Washes—					
3	2	1	½	¼	⅛		
Serum without addition ...	Tr.	Tr.	0	0	0	0	0
Serum + 1/40th of its volume of trypsin ...	Gr.	Gr.	Tr.	Tr.	Tr.	0	0
Serum + 1/20th of its volume of trypsin ...	Gr.	Gr.	Gr.	Gr.	Gr.	Gr.	0
Serum + 1/10th of its volume of trypsin ...	Gr.	Gr.	Gr.	Gr.	Gr.	Gr.	0

To this experiment may be added the following which brings out that there is a general but not a perfect correlation between the antitryptic power of the serum and its power of resisting infection by the bacillus of Welch.

#### Experiment 11.

Derivation of the serum.	Antitryptic power* of the serum.	Infection-resisting (physiologic) power.					
		Amount of culture implanted.					
		3	2	1	½	¼	⅛
Patient with serious compound fracture.	10 units (reciprocal of T/10).	0	0	0	0	0	0
Patient with perforating wound of chest.	6·6 units (reciprocal of T/15).	Tr.	0	0	0	0	0
Patient with gangrene infection of leg.	6·6 units (reciprocal of T/15).	Gr.	0	0	0	0	0
Patient with serious flesh wound.	5 units (reciprocal of T/20).	Gr.	Gr.	Gr.	Gr.	Gr.	Gr.
Patient with serious flesh wound.	5 units (reciprocal of T/20).	Gr.	Tr.	0	0	0	0
Normal man.	5 units (reciprocal of T/20).	Gr.	Gr.	Gr.	0	0	0

\* Here, as elsewhere, the antitryptic power was measured by finding out what dilution of trypsin was neutralised by an equal volume of serum. By dividing in each case the figure representing this dilution into 100 we obtain the reciprocals, figures which provide a very convenient expression for the results of antitryptic measurement.

#### (d) Experiments showing that the Growth of the Bacillus of Welch in the Blood-Fluids is Promoted by the Addition of Acid.

When one notes that the bacillus of Welch when growing freely in serum turns it acid; and when we then reflect upon the fact that all serum cultures of the microbe, whether *in vitro* or in the living body, begin with difficulty, and then, after reaching a certain critical point, progress at the rate of an avalanche, one inevitably, as in regard to the reduction of the antitryptic power of the serum, asks oneself whether the characteristic avalanche-like acceleration of growth may not be a direct result of this particular change in the medium. The answer is given in the following experiments.

#### Experiment 12. 1.

Seven unit volumes of serum were neutralised by the addition of 2 unit volumes of a N/10 sulphuric acid—the control sample of serum being diluted to the same extent with physiological saline solution. This done, the antitryptic power of the two samples of serum was measured. It worked out in each case as 3 (approximately)—i.e., a unit volume of

		Cultural results.						
		After-wash.						
		1st.	2nd.	3rd.	4th.	5th.	6th.	7th.
Neutralised serum ...	Gr.	Gr.	Gr.	Gr.	Gr.	Gr.	Gr.	Gr.
Correspondingly diluted serum ...	0	0	0	0	0	0	0	0

each of the sera neutralised a 40-fold and failed to neutralise a 30-fold dilution of the trypsin. These preliminaries completed, the resistance of the two sera to infection by the bacillus of Welch was investigated by aspirating into a capillary pipette a unit volume of a thick bacterial suspension, and following up in each case (I call this the after-wash method) by a series of unit volumes of serum.

These successive after-washes were divided off by bubbles of coal-gas introduced by the technique already explained (*vide* Footnote 3). The results after 24 hours culture were as shown in the preceding table.

#### Experiment 13.

As in the last experiment 7 unit volumes of serum were mixed in the one case with 2 unit volumes of N/10 sulphuric acid, and in the other with 2 unit volumes of physiological salt solution. The sera were then put away for 24 hours. The antitryptic power of each sample of serum was then tested. It worked out, in the case of the neutralised serum, as less than 3·3 units and greater than 2·5 units, in the case of the correspondingly control sample of serum as less than 4 units and greater than 3·3 units. Graduated dilutions of a suspension of Welch's bacillus were then made upon slides by the wash-volume (W/V) method—i.e., in each case a wash of bacterial suspension or implanted serum was carried over into a unit volume of serum to make the next dilution in series. An unmeasured sample of the whole series of dilutions was then drawn up into the stem of a capillary pipette, the successive volumes being separated by bubbles of coal-gas. The experiment was in the case of each serum carried out in duplicate. The cultural results were as follows.

#### Experiment 15.

This experiment given in tabular form below is self-explanatory.

Serum implanted with 3 washes of bacterial suspension ...	No growth.
" " " 2 " " "	" "
" " " 1 wash " " "	" "
Serum neutralised (by adding 2 volumes of N/10 sulphuric acid to 7 volumes of serum) and implanted with 1/5th wash of bacterial suspension	Copious growth.
Serum acidified (by adding 3 volumes of N/10 sulphuric acid to 7 volumes of serum) and implanted with 1/5th wash of bacterial suspension	Copious growth.

This series of experiments make it, as it seems to me, quite indubitable that additions of acid convert the serum into an eminently favourable medium for the bacillus of Welch, and it is clear from the data set forth in connexion with Experiments 12 and 13 that this effect is obtained quite apart from any reduction of the antitryptic power. We have seen that the converse of this last also holds true, the reduction of antitryptic power quite apart from any addition of acid, converts the serum into a very favourable culture-medium for the micro-organism. And I think there can be no question that when these two factors co-operate we have a combination which adequately accounts for the avalanche phenomenon, if I may so call it, which is the outstanding feature in the biology of the bacillus of Welch both when it grows in the blood-fluids *in vitro*, when it grows in the dead body, and when in the living body it invades the tissues, giving rise to spreading "gas gangrene." We have next to study the growth of the bacillus of Welch in the dead body.

### III. CONDITIONS WHICH GOVERN THE GROWTH OF THE BACILLUS OF WELCH IN THE DEAD BODY.

Already in Welch's very first publication upon the *Bacillus aerogenes capsulatus*—the microbe which now bears his name—it is put upon record that if a small volume of culture is introduced into the blood stream of a rabbit, and the animal is then killed and put into the incubator, the whole organism will be rapidly invaded, gas being generated in the blood, the condition known as "foaming liver" being produced, and the peritoneal cavity being, after six or more hours, blown out with gas. As soon as we set ourselves to think out what all this imports, we see that it must mean that the chemical changes occurring in the blood and liver after death transform the blood-fluids into an eminently favourable medium for the cultivation of the bacillus of Welch.

The following experiments show that this surmise is quite correct.

#### Experiment 16.

Rabbit No. 1.—The animal, injected intravenously with 3 c.c. of a broth culture of the bacillus of Welch, was killed five minutes after, and was then placed in the incubator. A sample of blood was taken before and a series of samples after injection. In each case film preparations were made and examined, and measurements of the antitryptic power and of the blood alkalinity were undertaken. These are recorded in tabular form below. In regard to the film preparations, it will suffice to say that no microbes were microscopically discoverable in any but the last specimen; here they were numerous. After six hours the animal was blown up with gas and the liver was foaming.

		Measurements of anti-tryptic power and chemical reaction of the serum.	
		Times when the samples of blood were collected.	Anti-tryptic power.
		Units.	
Immediately before injection	...	3	Alkaline, N/40

10 .. .. (heart blood)	...	1·6	Alkaline, N/50
3 hrs.	.. ..	1·6	N/60
6 .. ..	.. ..	—	"Acid."

\* Here and elsewhere in this paper the alkalinity of the blood was measured by the method described in the author's "Technique of the Test and the Capillary Glass Tube" (Constable, London).

We have here evidence that, presumably as a result of a destruction of leucocytes, the antitryptic power of the blood is progressively reduced, and that, no doubt as a consequence of lactic acid production in the muscles, the blood-fluids lose their alkalinity and finally become acid. One can hardly doubt that it is these changes which help forward the growth of Welch's bacillus in the dead rabbit. That the anaerobic conditions do not play here any responsible rôle will appear in connexion with Experiments 19 and 20.

#### Experiment 17.

Rabbit No. 2.—The animal was injected intravenously with 1 c.c. of an aerobically grown potato-broth culture, and was killed immediately after. As in the last case, film preparations of the blood were examined and measurements of the antitryptic power and alkalinity carried out. In films made 3½ hours after death hardly any microbes could be detected. In preparations made 4½ hours after death they numbered 6–8 to the microscopic field. At the end of six hours the animal was blown up with gas, and the liver was honey-combed with small cavities containing a foaming and tryptic fluid.

6 "	.. ..	2·2	Acid.

#### Experiment 18.

Rabbit 3.—This received intravenously 1 c.c. of a culture of the bacillus of Welch grown aerobically in potato broth, and the animal was killed 15 minutes after the injection and

placed in the incubator. Samples of blood were taken and examined as in the previous experiments. A single microbe was found in the blood film made 2 hours after death. The liver 7 hours after death was torn to pieces by gas and looked, except for the fact that its colour was a dark brown red, like a mass of coral as obtained from the swimmerets of a hen-lobster; films prepared from it showed an almost solid mass of microbes. The results of the measurements of antitryptic power and blood reaction are subjoined.

4 " " " " ... ...	1.6*	" Acid.

\* Measured after serum had been neutralised with washes of N/10 NaOH.

#### Experiment 19.

Rabbit 4.—A sample of blood was taken from this animal, and it was then, without receiving any injection, killed and placed in the incubator. The second samples of blood were taken 3 hours after death respectively from the S.V.C. and from the I.V.C. and hepatic vein. Sample 3 was taken from the heart 5 hours after death. The results of the measurements of antitryptic power, blood reaction, and infection resisting power are subjoined.

\* Determined after serum had been neutralised by washes of N/10 NaOH.

It is evident from the results set out here that the blood changes which convert the blood-fluids after death into an eminently favourable culture medium for the bacillus of Welch are chemical changes which occur spontaneously, and quite independently of the inoculation of the bacillus of Welch. Furthermore, when we consider the cultural results set out in the second of the two tables, bearing in view that the cultures were in each case made anaerobically, we recognise that the circumstance that the fact that anaerobic conditions such as these prevail in the dead body is a fact which can have nothing to do with the rapid pullulation of the microbe.

#### Experiment 20.

Here a sample of blood was taken from a cat and the animal was then immediately killed and placed in the

incubator. Sample 2 was taken from the heart three hours after; Sample 3 six hours after. As in the last case, the antitryptic power, the blood reaction, and infection-resisting power of these samples were measured. It will be seen that except for the fact that the antitryptic power is maintained unaltered the results are precisely the same as those obtained in the rabbit.

#### IV. CONDITIONS WHICH GOVERN THE GROWTH OF THE BACILLUS OF WELCH IN THE LIVING ORGANISM, IN PARTICULAR ON THE BLOOD CHANGES WHICH SUPERVENE (a) WHEN THE BACILLUS OF WELCH IS INOCULATED INTO THE BLOOD STREAM OR SUBCUTANEOUS TISSUE, AND (b) WHEN THE MICROBE INVADES THE TISSUES FROM A WOUND PRODUCING GAS GANGRENE AND THE CHARACTERISTIC TOXÆMIA WHICH IS ASSOCIATED WITH THIS.

Disposing my data in accordance with the scheme thus indicated I may set forth first, adding here and there brief comment, certain data furnished by blood examinations undertaken upon rabbits inoculated intravenously with cultures of the bacillus of Welch.

##### (a) Experiments in which the Bacillus of Welch was Inoculated Intravenously into Rabbits.

#### Experiment 21.

Rabbit 5.—This was a companion rabbit to Rabbit 4 (Experiment 18), and it was inoculated intravenously with 1 c.c. of the same potato broth culture as was there employed. A comparison of the figures given below with those given in connexion with Experiment 18 shows up to the 19 hours after the injection profound differences here, the alkalinity of the blood between the two remaining practically unaffected and the antitryptic power sinking away only very slowly. Thereupon, apparently quite suddenly the rabbit became collapsed and the circulation flagged so much that blood was unobtainable from the ears (these were stone cold) and had to be drawn off from the femoral artery. Respiration was 80 to 100 in the minute, and the clinical picture corresponded to that of the classical "acid rabbit" of Walther and Stadelmann—i.e., to the clinical picture seen when a rabbit is overdosed with hydrochloric acid. The details of the experiment are as follows.

Times when the samples of blood were collected.	Measurements of antitryptic power and alkalinity.	
	Antitryptic power.	Alkalinity of blood.
Immediately before injection ... ... ...	3.6	N 30
15 minutes after injection ... ... ...	2.2	—
4 hours " " " " ...	3.0	
19 " " " " ...	2.5	N 35
21 " " " " ...	4.0	N 50
23 ½ " " " (1½ hours after death)	1.6	N 180

Owing to the difficulty of procuring sufficient rabbits only two more experiments of this kind were made. Both of these, so far as the first hours of observation are concerned, confirmed the results of Experiment 21; but neither of them gave any evidence in corroboration of the view that death in infection by the bacillus of Welch is ushered in by an acidæmia. In view, however, of the circumstance that there were in each a formidable lacuna in the observations, the animal in each case dying unexpectedly in the night, the fact that evidence of the supervention of acidæmia is wanting must be discounted. The data relating to one of the two rabbits—a rabbit that was found dead in 18 hours after the intravenous injection of a small quantum of culture—are given below.

#### Experiment 22.

Times when the samples of blood were collected.	Measurements of antitryptic power and alkalinity.	
	Antitryptic power.	Alkalinity of blood.
Immediately before injection ... ... ...	3.0	N 40
10 minutes after injection ... ... ...	2.6	N 40
30 " " " " ...	2.0	N 40
2 hours " " " " ...	2.0	N 40
6 " " " " ...	1.5	N 45

We pass now from the consideration of rapidly fatal intravenous inoculations to which there is no obvious immunising response to study the effects of subcutaneous inoculations

in the case of animals who for the most part respond and survive.

(b) *Experiments in which the Bacillus of Welch was Inoculated Subcutaneously into Guinea-pigs and White Rats.*

Here also observations were made upon the antitryptic power and the alkalinity of the serum from the circulating blood. In addition—for it was possible to do this until

CHART I.

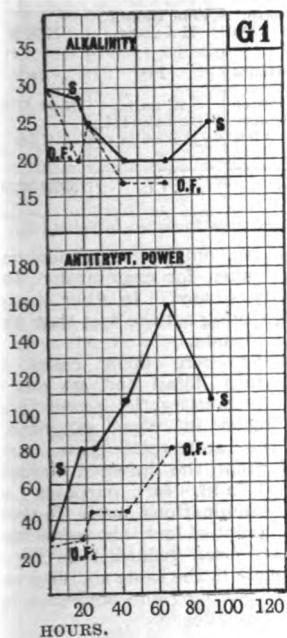

CHART II.

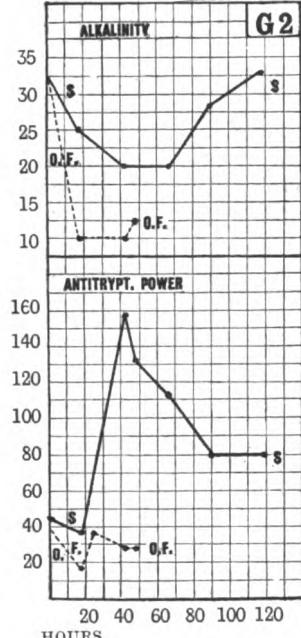

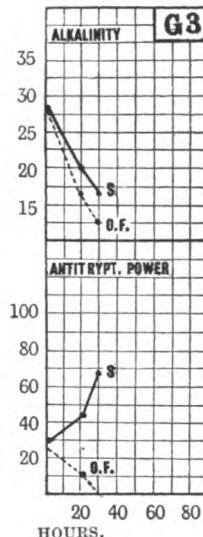

CHART III.

## Experiment 25.

Guinea-pig No. 3.—The animal was inoculated subcutaneously with 0.3 c.c. of a 24-hour-old potato-broth culture aerobically grown. Local effusion was well developed after 21 hours. After 27 hours the subcutaneous tissue, as soon as it became flaccid through withdrawal of fluid, filled up rapidly with gas, and the animal died 33 hours after the injection. (See Chart III., G 3.)

## Experiment 26.

White rat No. 1.—The animal was inoculated subcutaneously with 0.7 c.c. of a 24-hour-old potato-broth culture aerobically grown. Local effusion was well developed 16 hours after, and from the second day onwards the lesion became indurated and the oedema gradually disappeared, the animal making a perfect recovery. (See Chart IV., R 1.)

## Experiment 27.

White rat No. 2.—The animal was inoculated subcutaneously with 0.6 c.c. of a 24-hour-old potato-broth culture. The local lesion ran the same course as in the first rat, and the animal, after being very ill for two days, made a perfect recovery. (See Chart V., R 2.)

## Experiment 28.

White rat No. 3.—The animal was inoculated subcutaneously with 3/5ths of a 24-hour-old potato-broth culture. There was less effusion than in the case of the first two rats, and by the second day it had been completely absorbed. The animal was never really ill. (See Chart VI., R 3.)

It is brought out very clearly in these charts that infection by the bacillus of Welch produces as a rule both a local and a general acidosis, and it will be seen—and, of course, this was to be expected *a priori*—that we have always a more pronounced acidosis in the local lesion than in the general blood stream. Where, as in Chart III., the acidæmia becomes

CHART IV.

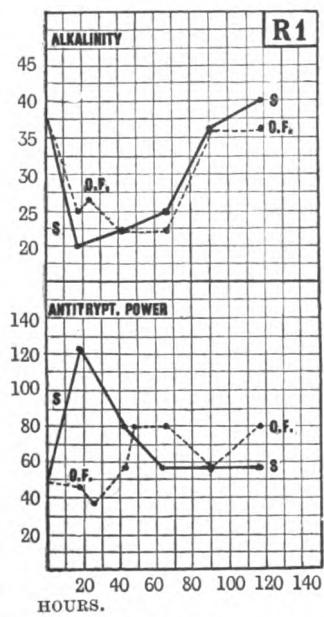

CHART V.

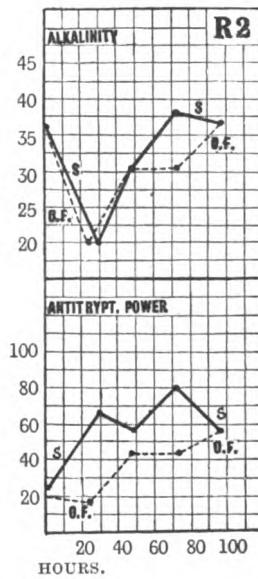

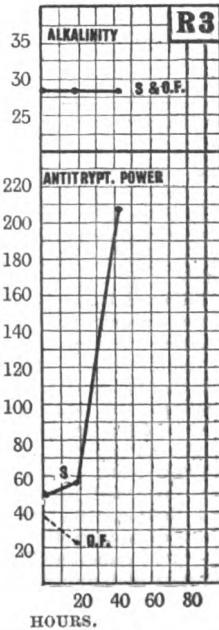

CHART VI.

such time as the local effusion was either absorbed or broke through the skin and was lost—determinations were made also of the antitryptic power and alkalinity prevailing at the seat of the inoculation. In each case the results are set out in the form of charts. Upon these the unbroken line is the curve obtained from the circulating blood; the interrupted line the curve from the oedema fluid. And in each case the scale is a scale of reciprocals—i.e., the figures are the quotients obtained by taking the dilution of the reagent which neutralised the effect of an equivalent volume of serum and dividing this into 1000.

## Experiment 23.

Guinea-pig No. 1.—The animal was inoculated subcutaneously in the leg with 0.1 c.c. of a 24-hour-old potato-broth culture aerobically grown. Beginning in the leg the effusion gradually spread over the whole of the belly, and finally after three days the skin broke down and the animal afterwards recovering and the wound healing over. The film preparations made from the effusion showed at first very numerous and afterwards only few bacilli. (See Chart I., G 1.)

## Experiment 24.

Guinea-pig No. 2.—The animal was inoculated subcutaneously with 0.3 c.c. of a 24-hour-old potato-broth culture aerobically grown. Local effusion was well developed after 18 hours; it increased in quantity up to the 48 hours and then broke through upon the skin and leaked away, the wound afterwards healing up and the guinea-pig making a good recovery. (See Chart II., G 2.)

very pronounced the animal succumbs. And where, as in Chart VI., there is no acidæmia the animal is never seriously ill. Turning to the antitryptic power, we see that in all cases without exception—and when we turn back we can see indications of this also in the rabbit experiments

(*vide* Experiments 21 and 22)—the curve which represents the antitryptic power of the blood rises. It rises very steeply where, as in Chart VI., the animal deals triumphantly with its infection; and it rises only very little where, as in Chart III., the animal puts up only a very feeble fight.

It also holds true of the curve of the antitryptic power of the oedema fluid in Charts I., II., IV., and V. that as the animal begins to recover it rises, following the curve of the blood, and we see in Chart III. that the oedema fluid may become tryptic in the case where the animal fails to stand up against the infection.

(c) *Observations Made on Man.*

We have now by experiments conducted *in vitro*, and in the dead, and living animals, collected sufficient data to enable us to construe aright such observations as it may be practicable to make upon men suffering from wounds infected by the bacillus of Welch, or from that spreading tissue infection which is spoken of as "gas gangrene," or again from that sharply characterised toxæmic condition which is the ultimate outcome of that infection.

A commencement may be made by setting out in tabular form the results of a series of antitryptic measurements made by me on three consecutive days in a casualty clearing station. These results relate to men all recently admitted to hospital with severe and highly infected wounds—cases of manifest "gas gangrene" being here specially excluded. I may further explain that many of the cases who were examined on the first day were examined also on the second, and similarly many of the cases examined on the second were re-examined on the third day. (See Table I.)

TABLE I.—*Measurements of the Antitryptic Power of the Blood of Normal Men, Slightly Wounded Men, and Heavily Wounded Men, excluding those affected with "Gas Gangrene."*

Date.	Normal men.		Slightly wounded men.		Heavily wounded men, excluding cases of gas gangrene.	
	A.T.P. of the individual men.	Aver-age.	A.T.P. of the individual men.	Aver-age.	A.T.P. of the individual men.	Aver-age.

Summary ...	...	4·7 units	—	5·8 units	—	11·3 units
Antitryptic index ...	1		1·23		2·4	

It is brought into clear view by the summary that—and I have already on previous occasions emphasised this point—every microbic infection of wounds (and the same probably holds of all microbic infections and inoculations of vaccine) is followed by a rise in the antitryptic power constituting a non-specific immunising response—that response being greater or less in accordance with the degree of the severity of the infection. Moreover, consideration of the figures for the successive days indicates that as the septic condition develops the antitryptic power gradually increases. I next take from the foregoing table its data relating to the antitryptic power in heavily infected patients not affected with "gas gangrene," supplement these with data furnished by measurements of their blood alkalinity; and then contrast these with data furnished by measurements of antitryptic power and blood alkalinity carried out on "gas gangrene" patients, adding also for comparison figures which apply to normal men.

These data are incorporated in Table II.

Scrutiny of this table reveals that there is with regard to antitryptic power absolutely no difference between heavily infected patients not suffering from "gas gangrene" and patients suffering from that infection. When, however, we turn to the column headed "Blood alkalinity," we see that while the blood alkalinity of the heavily infected patient corresponds exactly with the normal, in the "gas

TABLE II.—*Summary of Measurements of Antitryptic Power and Blood Alkalinity made upon Heavily Infected Patients not affected with "Gas Gangrene," and "Gas Gangrene" Patients respectively.*

	Antitryptic power.	Blood alkalinity.
Heavily infected patients exclusive of cases of spreading gas gangrene bacillus infection.	25 Number of patients examined. Range of variation within the group. Average for the group.	10 5·7-22·2 units. (Vide Table I.) 11·3 units. N/30-N/35 N/31·5
Patients suffering from spreading gas gangrene bacillus infection and intoxication.	14* Number of patients examined. Range of variation within the group. Average for the group.	15* 5-22 units. (Vide Table III.) 11·2 units. N/40-N/80 N/55
Normal men	4·7	N/30-N/35

\* The majority of these patients are those included in Table III.

"gas gangrene" patient, and, of course, only quite pronounced cases of "gas gangrene" were taken for examination, the blood alkalinity is very markedly reduced. In other words, the figures here brought together bring out the fact that the toxæmia of gas gangrene is an acidæmia.

In Table III., concentrating here upon cases of "gas gangrene," I go more into detail and set out a series of measurements of the antitryptic power and alkalinity of the circulating blood in "gas gangrene" and also measurements of the antitryptic power and alkalinity of lymph obtained from the infected tissues. At the end of the table I add, for purposes of comparison the details of the examinations made in two cases which might—though, in point of fact, the error was in neither case committed—have been regarded as "gas gangrene" cases. I further include in the table six observations bearing on the treatment of gas gangrene acidæmia by the intravenous administration of alkalies.

*Data Furnished by Measurements of the Antitryptic Power and Alkalinity of the Circulating Blood and of the Lymph from the Infected Tissues in Cases of "Gas Gangrene."*

Consideration of the data which are set out in Table III. makes, as I think, quite clear that we are, in the so-called "gas gangrene infection" of man, dealing with essentially the same phenomena as in our laboratory experiments. We saw in *in vitro* cultures in serum that the bacillus of Welch diminishes the antitryptic power of the medium and renders it acid; and we saw that the serum is by these means converted into a pre-eminently favourable medium for the growth of the bacillus. In experiments on the blood in the dead body we saw that it is these chemical changes which furnish the conditions required for the avalanche-like inroad of the bacterial infection. And, finally, experiments upon living animals showed that we have in infections by the bacillus of Welch, *with respect to alkalinity*, a reduction in the fluids taken from the focus of infection, and also a reduction in the circulating blood; and, *with respect to antitryptic power*, in the circulating blood, a marked immunising response, while we have in the infected tissues a diminished or abolished antitryptic power, especially where the animal is only unsuccessfully combating or succumbing to the infection.

Every one of these points obtrudes itself again upon our notice in the records dealing with human "gas gangrene" which are brought together in Tables II. and III. We have there, to begin with, the high antitryptic response in the circulating blood and the reduced or abolished antitryptic power in the infected tissues or infected effusions. We have, in addition, diminished alkalinity in the infected tissues or infected effusions. And we have not only a local acidosis, but we have also an acidæmia. We find that acidæmia where the infection has culminated in that "gas gangrene toxæmia" which is ushered in by vomiting and then shows itself in collapse, with rapid respiration, ashy-grey pallor, feeble and then impalpable pulse, the body becoming stone-cold before death, first the hands and feet, then the whole limbs, finally the nose, ears, and forehead, the patient remaining with clear intellect and without suffering to the last.

It may perhaps, pending further investigation, be assumed with respect to this acidæmic condition that the acid production proceeds not only in the infected tissues standing in

TABLE III.

Serial number	Brief outline of the case.	Data with regard to the antitryptic power and alkalinity of the blood.	Data with regard to the antitryptic power and alkalinity of the lymph in the infected tissues.
1	Spreading gangrene bacillus invasion in subcutaneous tissue of arm, with coppery discolouration and crepitus. Amputation of arm.	A.T.P., 8 units.	Edema fluid from tissues close to the wound : Tryptic. Edema fluid from spreading edge : A.T.P., 2. (Edema fluid from tissues above the wound : A.T.P., 1.6.)
2	Clinical features as in Case 1.	A.T.P., 6.6 units.	Before intravenous injection : Alkalinity, N/80; A.T.P., 6.6 units. 10 minutes after injection : Alkalinity, N/50; A.T.P., 6.6 units.
3	Multiple shrapnel wounds of leg with spreading gangrene bacillus infection in subcutaneous tissue. Acute toxæmia, with rapid respiration, impalpable pulse, and cold creeping upwards from extremities. Intravenous injection of 16 grammes of NaHCO <sub>3</sub> . Death 12 hours after onset of toxæmic symptoms.	A.T.P., 11.4 units. Alkalinity, N/50.	Fluid from knee : A.T.P., 2 units; Alkalinity, N/50. Fluid from subcutaneous tissue : A.T.P., 3.3 units; Alkalinity, N/40.
4	Extensive wound of thigh. Spreading gangrene bacillus infection involving knee and spreading in subcutaneous tissue of the thigh with crepitus. Amputation of thigh. Death 48 hours after operation.	—	—
5	Compound fracture of thigh with extensive flesh wound. Rapidly spreading gangrene bacillus infection of tissues. Acute toxæmia. Icteric serum*; culture of the bacillus of Welch from blood 4 hours, intravenous injection of 8 grammes of NaHCO <sub>3</sub> 8 hours, and death 14 hours, after onset of toxæmic symptoms.	Before intravenous injection : A.T.P., 5 units; Alkalinity, N/50. 5 minutes after injection : A.T.P., 5 units; Alkalinity, N/50. 6 hours after injection : A.T.P., 5 units; Alkalinity, N/50.	—
6	Compound fracture of ankle. Acute toxæmia with collapse, precluding operation. Injection of 20 grammes of lactate of soda. Condition rapidly improved and amputation carried out. In evening patient was sitting up, next morning general condition very satisfactory, and patient made a good recovery.	Before injection : Alkalinity, N/50. Immediately after : Alkalinity, N/50. 7 hours after : Alkalinity, N/50. Next morning : Alkalinity, N/40	—
7	Extensive wound in upper third of arm. Gangrene with dark livid discolouration and hemorrhagic blisters, with purple mottling extending over the shoulder. Profound toxæmia; 10 grammes of NaHCO <sub>3</sub> intravenously. Disarticulation at shoulder. Next morning general condition satisfactory and patient made a good recovery. Very numerous shrapnel wounds of both legs. Gangrene bacillus infection spreading out from these in the form of infiltrated copper-coloured patches.	At time of operation : Alkalinity, N/70. 6 hours after : Alkalinity, N/60. Next day : Alkalinity, N/40.	Edema fluid from upper arm : Alkalinity, N/200. (Edema fluid from lower arm : Alkalinity, N/60.)
8	Gangrene of leg spreading upwards. Amputation at middle of thigh.	A.T.P., 20 units; Alkalinity, N/50.	Edema fluid from infiltrated copper-coloured patches : A.T.P., 6.6 units; Alkalinity, N/60.
9	Massive gangrene infection of all muscles of anterior aspect of thigh.	A.T.P., 8 units.	A.T.P. of edema fluid from spreading edge, 2.9 units.
10	Hemothorax infected with Welch's bacillus and containing many W.B.C. Icteric serum.	Alkalinity, N/60.	Clear fluid from wound : Alkalinity, N/60. Pleural effusion : A.T.P., 6.6 units; Alkalinity, N/100.
11	Hemothorax film preparations show 20 or more R. Welch in each microscopic field. No indications of growth in effusion when cultured, and growth on artificial media only when very large quanta are implanted.	A.T.P., 22 units; Alkalinity, N/40.	A.T.P., 8 units; Alkalinity, N/100.

TABLE III.—(Continued).

Serial number	Brief outline of the case.	Data with regard to the antitryptic power and alkalinity of the blood.	Data with regard to the antitryptic power and alkalinity of the lymph in the infected tissues.
13	Patient admitted with an enormous wound in groin and in a condition of collapse. Recovered sufficiently to allow of incomplete operation. 24 hours later vomiting and very feeble, rapid pulse. Intravenous injection of 20 grammes of NaHCO <sub>3</sub> . Next day some improvement. Day after patient succumbed.	Alkalinity, N/40 of blood collected circ. 18 hours after operation.	—
14	Amputation after 4 days in hospital of thigh for gas gangrene starting from wound of leg and knee. 24 hours after patient was still very weak. 40 hours after operation 10 grammes of NaHCO <sub>3</sub> intravenously. Patient succumbed 24 hours later.	Blood taken at time of operation : A.T.P., 16 units; Alkalinity, N/60. Blood taken 24 hours after operation : A.T.P., 20 units; Alkalinity, N/60. Blood taken immediately before injection : A.T.P., 20 units; Alkalinity, N/50. Blood taken immediately after injection : A.T.P., 23 units; Alkalinity, N/40.	Fluid from edematous subcutaneous tissue just above level of amputation : A.T.P., 13.3 units; Alkalinity, N/80.
15	Amputation stump of upper part of thigh with gas infection of the sloughing surface. An axial incision carried up from this upon ilium. (Edema fluid neutralised by lactic acid gives anaerobically in 4 hours a foaming culture of R. Welch. Unneutralised it gives anaerobically a scanty growth in 18 hours. Heart blood obtained 24 hours later at P.M. gives a pure culture of streptococcus.	A.T.P., 16 units; Alkalinity, N/35.	Edema fluid intermixed with blood from incised tissue : A.T.P., 16 units; Alkalinity, N/35.
16	Perforating wound immediately below the knee. Limb cold and edematous. Amputation with view to possibility of gas gangrene infection.	A.T.P., 8 units; Alkalinity, N/35.	A.T.P., 4.4 units; Alkalinity, N/35.

\* The special features of the blood in gas gangrene toxæmia are that the serum is of a characteristic deep yellow colour, there being also, as in most cases of serious bacterial intoxication, a very heavy buffy coat.

relation with the wound, but also in the liver and other internal organs to which the bacillus of Welch may have been conveyed—metastatic growth being favoured as soon as the alkalinity of the blood begins to be reduced by the influx of lymph charged with acid in the infected tissues.

Considerations of this kind should be present to our minds when we turn to take stock of the results of the therapeutic administration of alkalis in "gas gangrene." As shown by the records, this procedure gave markedly favourable results only in two cases out of the six. In those two cases, however, the effect was dramatic. Probably in the other cases, as is the case in the acidæmia of diabetes and uræmia, the evolution of acid must have gone on unaffected.

It must be left for future experimentation to determine whether better results can be obtained by earlier intravenous injection of alkali, and whether the local evolution of gas gangrene could be arrested by the injection into the tissues or, as the case may be, into an infected hæmorthorax of alkali or of an alkalinised strongly antitryptic serum, remembering here that a strongly antitryptic serum can practically always be obtained either from the patient himself or from any other heavily infected patient.

In concluding, I have to express my acknowledgments to my colleague Major Georges Dreyer for generous assistance in plotting out the curves and in some of the experiments; to my fellow worker the late Captain H. H. Tanner for similar assistance. My thanks are also due to Captain Haycraft for help in connexion with the study of cases of gas gangrene, and to my fellow worker Dr. Alexander Fleming for permission to incorporate in this lecture some of the results of his research work.

## ORTHOPÆDIC METHODS IN MILITARY SURGERY.<sup>1</sup>

BY D. McCRAE AITKEN, M.B., CH.B. EDIN., F.R.C.S.

LET me first express to you my appreciation of the honour of giving a demonstration of orthopaedic methods in military surgery before this distinguished society. I fear that there must be some lack of continuity in the arrangement of my remarks. In selecting cases for demonstration, I have been guided first of all by the material available in my wards at the Military Orthopaedic Hospital. I regret that I have neglected to keep photographic records of many cases which would have been interesting. The consideration, however, which has been most prominent in my mind, is that at no time in the history of this country has conservative surgery been a matter of such vital economic importance.

I have, therefore, selected cases by which I hope to prove that with patient perseverance in gentle methods it is possible to arrive at restoration of function which would be impossible by any violent means of attack, or any direct operative procedure however brilliantly designed. In orthopaedic surgery operation is always a mere preliminary to clear the way for educative treatment to restore function; it is not a direct curative measure.

### *Injuries of the Shoulder.*

The first series of cases illustrates the conservation of the deltoid muscle after injury, and the restoration of its function where lost from disuse following severe injury. The line of treatment follows that employed in cases of poliomyelitis or in fracture-dislocation of the shoulder, the guiding principle being that in all serious lesions about the shoulder the abducted position of the arm is a safe position for treatment, though not always the easiest to maintain. For example, we have long known that a shoulder ankylosed with the arm by the side leads to a very useless limb, while if ankylosed with arm abducted, in such a position that with the elbow flexed the fingers come easily to the mouth, the mobility of the scapula is developed so as to make up for the loss of the shoulder-joint. Thus, after ankylosis of the shoulder we have been in the habit of performing a cuneiform osteotomy of the humerus and abducting the arm so as to secure union in the abducted position.

In children full abduction is permissible, for in two or three years they develop an extraordinary compensatory mobility of the scapula. In adults the arm should be raised to rather less than a right angle, otherwise the elbow may not come quite down to the side when the scapula is dropped, and the patient goes about as if he were offering his arm to a partner for dinner, which might be embarrassing.

CASE 1.—I regret that I have no photographs before treatment was commenced. Nov. 19th, 1915: Gunshot wound of right shoulder; suppuration, removal of head of humerus. April 11th, 1916: Admitted five months after injury. No voluntary abduction; wounds not quite healed; scar in muscles firmly adherent to subjacent bone. Passive abduction only 45° without pain. April 19th: Gradual abduction; on abduction splint. (Fig. 1.) July 1st: Lifts arm off splint. (Fig. 2.) August 30th: Discharged; able to put hand to his back collar-stud and brush his hair.

CASE 2.—Sept. 8th, 1916: Fractured scapula, &c. Fracture through spine and body of scapula, septic, patient ill, shoulder dropped. Fractured ends of bone exposed and bare; wound a large round gap. Sept. 18th: Admitted. Elbow supported. Pain relieved by lifting arm and shoulder on abduction pillow in the axilla; at same time gap in scapula closed and bones which were exposed have granulated over. (Photograph shown.) Sept. 22nd: Haemorrhage. Sept. 23rd: Abduction splint applied (Fig. 3), as it was now more easy to abduct the arm, and the wound was more healthy under irrigation and frequent dressing with hypochlorite lotion.

CASE 3.—April 26th, 1915: Wound of left shoulder. Three operations. Head of humerus removed August 23rd, 1915, as shown in X ray plate. (Fig. 4, skiagram.) June, 1916: Admitted. Put on abduction splint. August 23rd: Can lift arm off splint, but posterior part of deltoid overpowers anterior part. (Fig. 5.) I am trying to devise a light apparatus to hold the butt of the humerus more steadily against the remains of the scapula, so that a fairly efficient false

joint may result. As you see in the cast, the upper end of the humerus falls too low in the axilla when the muscles are relaxed.

CASE 4.—August 15th, 1915: Dardanelles. Two operations to remove bone, as shown in X ray. June 22nd, 1916: Admitted. Abduction splint. July 30th: Signs of recovery in deltoid. August 14th: Subperiosteal abscess in upper part of humerus opened and muscle recovery all abolished. (Photograph and patient shown.) This patient is now being kept in the splint to await the results of this inflammatory attack, and I am not curious to know whether he can move the shoulder or not, for even if it result in ankylosis his position is a good one. If I were to move his shoulder before voluntary movement returns I should only do harm.

CASE 5.—Feb. 1st, 1916: Gunshot wound of right shoulder. Sept. 15th: Admitted. No voluntary power in deltoid, as is manifest from the flattened appearance of the shoulder. (Figs. 6 and 7.) Put on abduction splint. (Fig. 8.) You will now see the muscle twitches returning, if you look carefully, when the patient makes a voluntary effort to raise the arm. This returning power is being carefully encouraged by massage, but he is never allowed to lower his elbow, which would stretch the weak muscle and probably paralyse it again by over-stretching it.

### *Injuries about the Elbow-joint.*

Passing next to the elbow-joint, I am tempted to digress first in a little personal history. In 1897-98, when a dresser in the surgical wards in Edinburgh, I was taught that every injury about the elbow, except fracture of the olecranon, should be treated in the fully flexed position. This doctrine had, I believe, been introduced by Caird and Cathcart, who had brought it from Liverpool. The second part of the Liverpool teaching, however, had escaped the Edinburgh teachers, and I look back with horror on the industry with which I performed daily passive movements on an unfortunate child with a split fracture of the condyles of the humerus, with the inevitable result that the joint became more painful and more stiff.

Three years later, when I became house surgeon to Robert Jones in Liverpool, I was taught the doctrine of rest. That is, that having flexed an injured elbow it must be left alone for three weeks or more, till all tenderness about the joint has disappeared. Then, and not till then, the sling may be slackened a few inches; if, two days later, the patient can move the hand through those few inches, the sling may be further slackened. If, however, the elbow become stiff in the new position, it must be again flexed and left to rest for another week or more before again testing it for mobility.

When in 1907 I walked round London hospitals, when I was a candidate for the Fellowship examination, I was surprised, and may I say horrified, to find that the internal right-angled splint was still being recommended for injuries of the elbow. I am still more horrified to find it in use to-day. I know of no injury about the elbow in which the internal right-angled splint can be regarded as a proper splint.

For this strong and sweeping statement there are two good reasons. The first is that the prominent internal epicondyle is pushed outwards, and the line of the elbow-joint distorted if the fracture is through or above the condyles; the second is that even if the epicondyle be to some extent accommodated in a hole in the splint, the forearm is fixed half way between supination and pronation, with the palm of the hand against the splint.

I would lay it down as a standing rule that in all injuries of the arm and elbow, and most of the forearm, the forearm must be supinated and the palm of the hand must be directed towards the face. If this is neglected there will be an error in the carrying angle of the elbow, or there will be limitation of the supination in the forearm, a very serious disability of which we have dozens of examples sent to us in the Military Orthopaedic Hospital. I know it is not always easy or possible to attain this, but I am certain that many surgeons are not consciously and deliberately trying to secure full supination in the early stages of treatment.

The next case I show is one of compound fracture immediately above the condyles.

CASE 6.—Sept. 3rd, 1916: Somme; salt pack, No. 5 Rouen. Sept. 18th: Admitted. Wounds pouring pus, and bare bone ends visible. Put on humerus extension splint for irrigation and dressing with hypochlorite solution. Oct. 8th: Wounds granulating, and looking cleaner. Rearranged under anaesthetic and put in flexed position with forearm supinated, and

FIG. 45.

wrist slung as he is now (patient shown); next day the X ray you see was taken. (Fig. 9.)

CASE 7.—August 17th, 1915: Gallipoli; operation to remove bone. Later wired; elbow stiff on admission just beyond right angle. May 1st, 1916: Admitted. (Fig. 10.) Wire felt at bottom of sinus and pulled out one day in June when it was loose. July 20th: Sinus healed. The X ray shows the apparently hopeless destruction of the joint. Short sling with rotation turn to supinate forearm. Movement returning as you see (patient shown). One Saturday I got a note from Dr. Mennell, who is in charge of the Massage Department, that he thought we were going too fast with movement, as the range was decreasing; he will therefore have a further period of rest in a short sling.

CASE 8.—Motor-cycle accident. I merely show this case as an example of the conundrums one may have to deal with. Meantime the patient has fallen and broken something loose, and I am having the arm extended in the hopes of reducing subsequent difficulties. The X ray shows the olecranon in position and the coronoid dislocated in front of the humerus, with a fracture of the shaft about 2 inches lower down, which makes manipulation of the upper end practically impossible. (Fig. 11.)

CASE 9.—March, 1916: Shrapnel entered above internal condyle; removed back of elbow. On admission could flex to 45°, extend to 120°. (Figs. 12, 13, and 14.) Has been fully extended once, then flexed for fear of stiffness. The elbow is now being definitely extended, as full flexion was recovered without difficulty after the first gradual extension. The picture shows the method of straightening an elbow (Fig. 15) in a straight Thomas arm-splint. In the patient who is now before you note that in one week, since the photograph was taken, the arm has become quite straight.

#### *Cases Illustrating Points in Treatment.*

The next series of cases I am showing because in each I made an error of judgment or in technique. I have learned from them and others may learn also.

CASE 10.—August 10th, 1915: Dardanelles. Developed typhoid 10 days after arrival in England. June 13th, 1916: Admitted with malposition and non-union shown in the picture. (Fig. 16.) Wounds had been healed only three months. As I did not intend to do an open operation, I thought I might risk reducing the deformity. June 26th: Straightened arm manually under anaesthetic. June 28th: Arm swollen, bullæ, wounds broken down and there was profuse discharge of pus. Now ulna united and line straight. Several small sequestra have come away.

CASE 11.—Oct. 13th, 1915: Bullet fractured right ulna. August 1st, 1916: Admitted bone ununited. (Fig. 17.) August 7th: Lateral graft from tibia; broke graft in getting it out, therefore shorter than was planned, as seen in the second X ray. (Fig. 18.) A broad osteotome is essential for picking out graft. The blade should be 2 inches broad. At the time the broadest osteotome available was only 1 inch, hence the accident. Oct. 10th: United: exercise. Now you see the nature of the movements possible. (Patient shown.)

CASE 12.—August 15th, 1915: Dardanelles. Gunshot wound of left arm. Operation at base; later operation to remove dead bone. June 1st, 1916: Admitted. Wounds healed. Defect in radius, as shown in X ray (Fig. 19), of about 3 inches of the shaft. June 19th: Graft from tibia; lower end inserted into marrow cavity, which was a mistake. It should have been inlaid along the lower fragment down to the styloid process. At the time of operation the alignment was good. The way in which the medullary bone has yielded is visible in the X ray (Fig. 20), giving rise to distortion and delay in union. The man can, however, use the hand and movements are improving every week. The flexor of the thumb, which had no origin before operation, is now acting, having taken a new origin from the grafted radius.

#### *Injuries of the Wrist.*

At the wrist in most instances stiffness in a flexed position is the fault to be avoided, and dorsiflexion is the first preliminary to any treatment. It is no use wasting time on massage till the wrist has been dorsiflexed. Every school-boy knows that the grip of the hand is weakest with the wrist flexed.

CASE 13.—Jan. 28th, 1916: fracture of right leg; shrapnel wound of left leg; compound fracture of wrist. On admission wrist flexed; could barely move fingers. Injury, fracture of lower end of radius and carpus. Supination very limited. (Photograph and X ray shown.) Oct. 15th: Anaesthetic; wrenched into dorsiflexion with Thomas wrench and put into plaster. Can now move fingers better than before. (Patient shown.)

While the epidiascope is being got ready I shall demonstrate the use of wrench on a wrist.

CASE 14.—Wounded May 3rd, 1915, Cameroons. X rays: (1) at base (Fig. 21), June, 1915; (2) (Fig. 22), August, 1915; (3) (Fig. 23), August, 1916. The treatment was exactly the same, wrenched three weeks ago yesterday. You now see how he can move his fingers independently after three weeks. Before the wrist was dorsiflexed he could barely move them all together at the interphalangeal joints and had no independent movement of individual fingers. The question of making a false joint at the base of the thumb is deferred till the present treatment is completed.

#### *Injuries to the Lower Limb.*

In the lower limb the problem of restoration of function is often much more simple than in the upper limb. If a man has a disability which precludes walking any arrangement which makes him independent of crutches is a boon. In my cripple hospital for children I do not think you will find a single pair of crutches. The reason for this is that if a child is allowed to swing along on crutches he will not bother about learning to use his limb properly. The same is in large measure true of the soldier. Unfortunately the hospitals are over-supplied with crutches. It is very difficult to prevent a man from getting hold of them; if he has not crutches of his own he borrows them, and then he does not educate his defective limb as he should.

CASE 15.—Patient came into hospital having had the head of his femur destroyed and removed in 1915. The shaft of the femur telescoped up and down nearly 4 inches and he could only walk on crutches. He was sent out in a walking calliper.

CASE 16.—May 2nd, 1915: Mesopotamia; bullet wound fracture of thigh between the two trochanters. March 16th, 1916: Sciatic nerve explored in New Zealand; Mr. Herbert reported that he could not find any trace of the nerve for several inches. July 20th: Admitted, 14 months after he was wounded. Hip coxa vara deformity shown in X ray and shortening 3½ inches. (Fig. 25.) Foot in equinus position (Fig. 24); complete sciatic palsy. July 24th: Foot wrenched into right-angled position; subcutaneous division of plantar fascia. August 7th: Osteotomy of femur; extension or abduction splint. (Shown in the paintings.) Oct. 6th: Real shortening about 1 inch; put in plaster. Will soon get up in walking calliper. I have been afraid to trust body weight on the union yet, as the second X ray (Fig. 26) shows there is still a lot of consolidation of bone-tissue to take place. Note the correction of the coxa vara.

CASE 17.—Feb. 15th, 1916: Mesopotamia; bullet wound; fracture in middle of shaft of femur; healed in three weeks. Sept. 5th: Admitted; shortening 2½ inches. (Fig. 27.) Angling both lateral and antero-posterior, as shown in pictures and X ray. (Figs. 28 and 29.) Sept. 8th: Operation; disunion of the callus with chisel; extension on Thomas knee-splint. (Figs. 30 and 31.) Oct. 23rd: Up in walking calliper; shortening ½ inch. Note that there is still an overlap. The shortening found on measurement was due more to faulty alignment than to overlapping of fragments.

CASE 18.—August 23rd, 1915: Thigh shattered below trochanters. August 22nd, 1916: Admitted with malunion shown in pictures. (Figs. 32 and 33.) Sinus only healed three days. Sent out in a walking Thomas splint (Fig. 34) for six months before I dare perform the obvious operation to bring the two parts of the bone in line. By rough measurement there should be less than 1 inch of shortening after operation.

CASE 19.—April 21st, 1916: Bullet through upper part of suprapatellar pouch; no history of fracture sent with the case. May 4th, admitted 13 days later, on a back splint: knee full of fluid. X ray, taken as a precaution before starting movement, showed the fracture. This, of course, made us postpone active walking and movement. (Picture shown.) Note it is a subperiosteal fracture, presumably produced by the expansion thrust of the bullet as it passed. It did not hit the bone.

The next case illustrates the use of the Thomas walking calliper in a case of fibrous ankylosis of the knee in which, although the knee was stiff, there was pain from straining of the fibrous union.

CASE 20.—January, 1915: Bullet entered the back of lower part of thigh; exit through upper part of knee in front. May 20th, 1916: Admitted 16 months after injury. (Fig. 35.) Complete fibrous ankylosis; slight valgus deformity; pain on walking indicated that the fibrous union was being strained. Sent out in walking calliper. (Fig. 36.) To report in six months, when I am quite prepared to find that with a complete relief from all strain the fibrous union has relaxed and a small amount of movement may be present. If that

is the case, I shall then try to increase the range of movement, but the presence of pain indicates that attempts at increasing movement now will only irritate the fibrous tissue and lead to the formation of more dense deposits.

*Turner extension splint.*—The next two pictures illustrate the use of the Turner extension splint for extending stiff flexed knees. It is of value in cases where the stiffness is due to fibrous deposits in and about the joint and in the muscles. It is therefore particularly applicable in cases where there has been diffuse fibrosis, the result of long-continued sepsis of low intensity. (Figs. 37 and 38.)

*Flexion splint.*—The next splint I show is one useful for flexing stiff knees where there has been fracture of the femur, and the vasti and rectus muscles are all matted together and to the bone in one solid mass of fibrous infiltration. The splint is applied and the limb very slowly flexed for some days. Then the splint is removed and the limb allowed to straighten. Then the process is repeated, each time carrying the flexion about 5 to 10 degrees farther than the former; and so on for three to five months, when gradually some regeneration of muscle occurs as the cicatricial tissue gets loosened. After this, massage and exercise carry the process farther. The advantage over the McIntyre, from which it is copied, is that the patient can get about in the splint. It is only applicable to old cases with dense fibrosis, and is not intended for recent cases which are amenable to treatment by massage.

The next cases are a series of deformities of the leg resulting from malunion of fractures.

CASE 21.—Sept. 24th, 1915: Fracture of both bones of left leg; many pieces of bone removed. June 7th, 1916: Admitted; wound not healed; foot in extreme position of claw foot and toes also flexed. (Figs. 39 and 40.) June: Foot wrenched into right-angled position and put in plaster. Fig. 41 shows the result. Fracture too firm to yield and too septic to be forcibly dealt with. Oct. 9th: Sequestra removed from the bone.

CASE 22.—July, 1915: Buried in trench by high-explosive shell; multiple fracture of left leg; foot crushed. August 30th: Admitted; leg too straight, does not show the natural bow of the tibia; is therefore a valgoid deformity. Foot had a ridge across the dorsum due to displacement of the bases of the metatarsals. (Pictures and cast shown.) These deformities are well shown in the picture and X ray and cast. August 31st: Foot wrenched to correct displacement of tarsus and metatarsus; put in plaster. Oct. 6th, 1916: Plaster removed; shape of foot much improved, but not perfect; wrenched again; put in plaster, which you now see on the patient and in the picture before you. Note the shape of the foot. There is no evidence of the hump in the plaster.

The next two cases illustrate the method of dealing with the troublesome deformities arising from trench foot. They follow the well-known routine lines of treatment of the acuter forms of flat foot, such as may follow an infective periarthritis, a crush, or the idiopathic forms sometimes seen. In the early stage, when the foot is too tender to touch, the patient is rested in bed absolutely, is massaged daily, and the shape of the feet gradually corrected with some suitable form of splint according to the deformity. When not too tender to be handled, though still too tender for the patient to stand on, the foot is moulded more firmly into correct shape in plaster-of-Paris bandages, and moulded by the surgeon's hands while the plaster is setting. Later the patient is able to get about in a walking plaster, such as those you will see.

CASE 23.—November, 1915: Trench foot; remained in France through the winter; discharged in March, 1916. Sept. 14th, 1916: Admitted; able to stand, but not able to walk much. Right foot is a typical claw foot and the left foot an extreme valgus as shown in the picture. (Fig. 42.) Sept. 20th: Both feet corrected in plaster. Oct. 11th: Plaster removed; right foot recovered (Fig. 43); ordered boot with bar on sole to maintain extension at the mid-tarsal joint. Left foot again put in plaster and will probably be ready in a fortnight for treatment in a boot with the heel raised a third of an inch on the inner side to maintain the inverted position which you see in the picture and in the patient's foot.

CASE 24.—November, 1915: Trench foot. On admission feet almost too tender to be touched; hallux valgus in both feet with the great toe tucked under the second and third. Treatment adopted: (1) Gradually straightened on splints and massage; (2) further moulded in plaster; (3) walking plasters in which you see the patient now. (Picture and patient shown.) Note that the hallux valgus splint has been incorporated in the plaster, as the deformity was tending to recur while the patient walked about in the previous plaster

splints. A plaster splint usually gets worn out in three to four weeks, less if the weather is wet, and must be immediately renewed with further correction if necessary, or the case will begin to relapse.

The methods of twisting and moulding a foot by means of plaster bandages are simply an application of familiar methods of correcting club-foot in infants, either with bandages or with sticking-plaster. It is only an application to plaster bandages of methods in everyday use by surgeons who are accustomed to use the direction and tension of their bandages for purposes of correcting or checking deformities. With your permission I will now give you a demonstration of the method with ordinary calico bandages, leaving to your imagination the firm control which can be got by plaster bandages when they set, as is shown in the case before you (Case 25), and in the pictures of the plaster being applied to this case.

The next case is that of a foot which I was urged to amputate on May 4th.

CASE 26.—The patient had been hit by a high-explosive shell on the left foot on April 30th, 1916. He was admitted to hospital on May 4th, 1916, with the forepart of the foot only attached by the soft parts of the sole. The head of the astragalus and the bases of the metatarsals were exposed in the wound. (Fig. 44.) Of the scaphoid and cuneiform bones there only remained a few scattered fragments. The wound surfaces were black and gangrenous and the whole foot extremely septic. The foot was fixed in position in a long crab splint and kept in it with continuous irrigation for several weeks. Formal dressings were only done at intervals; an anaesthetic was necessary on each occasion. Sequestra, of course, have come away on several occasions. I am now able to show you the kind of foot which is resulting from this continuous maintenance of one position. (Fig. 45.) You will note that the tendons are working on the forepart of the foot through the scar.

If I were to allow this patient to be without a splint and let the foot hang on the scar I believe that the scar would become more dense and that this mobility would be lost. In support of this statement I would quote an exactly similar case which was admitted to the hospital early in the spring. There was a similar scar across the dorsum of the foot. The scar was some months old, white, pucker and closely and firmly adherent to the subjacent bone, and there was, of course, no movement in the forepart of the foot in front of the scar. The toes were flexed and rigid and rather puffy. The treatment I adopted was to fix the foot in dorsiflexion in plaster-of-Paris and let the patient walk, the result being that in about two months' time the scar relaxed and the muscles began to act on the forepart of the foot through the scar. It was possible to follow this up by massage and exercise, and the patient left hospital with a shortened but very serviceable foot. I am extremely sorry that I did not keep photographic records of this case, as I consider it one of the most instructive that I have ever had, as it is a direct illustration of the principle that scarred tissue with a strain on it seems to feel a sense of responsibility and becomes hard and tough, while if relieved of the strain of this responsibility it relaxes and allows the muscles an opportunity of showing what they can do.

I trust that the cases I have demonstrated may serve to show that much can be accomplished towards the restoration of function in limbs which at first sight appear to be hopelessly impaired. These results can only be obtained by patience, perseverance, and an unwavering adherence to the plan of treatment without any intermission. The plan of treatment must be based on a firm belief in the principles of conservative surgery and in the value of rest, as first taught by Hilton and put in practice by Hugh Owen Thomas.

Before I sit down let me draw your attention to this old engraving, date 1783. It appears to be a sketch on Buzaglo's treatment of arthritis. According to the American Surgeon-General's Catalogue, he published in London a treatise on gout, and was sufficiently famous or notorious to be mentioned in Cruickshank's illustrations of the "Dance of Death." I have never been able to secure a copy of his book. I ask you to note the abducted position for treatment of the shoulder and hip, the right-angled shoe, and the splint in the corner, which is a rough forerunner of the Thomas knee splint. I would like to know more of this Buzaglo and his work, for he evidently knew and practised in 1780 some, at least, of the methods which have been reintroduced by Owen Thomas and Robert Jones and the school of surgeons who follow their teachings, among whom I take leave to include myself.

**REPORT ON SIX CASES OF  
AMOEBA HISTOLYTICA CARRIERS  
TREATED WITH EMETINE BIS-  
MUTHOUS IODIDE.**

BY CAPTAIN C. G. IMRIE, C.A.M.C.,  
AND  
LIEUTENANT W. ROCHE, R.A.M.C.

(Report to the Medical Research Committee.)

THE introduction of emetine in the treatment of amoebic dysentery marked an important advance in the treatment of this disease. In its action on the *Entamoeba histolytica* this alkaloid enjoys the rôle of a specific. However, experience has shown that emetine, as it is at present employed, does not always effect the destruction of this protozoan in its encysted stage. Thus, convalescents may continue over a considerable period of time to pass these cysts, which, as we know, are capable of transmitting the infection. From an epidemiological as well as a medical viewpoint the desirability of accomplishing the destruction of the entamoeba in the encysted stage is quite obvious.

It has been suggested by Dale that the failure of emetine by hypodermic administration to destroy the cysts of entamoeba may be due to the presence of the latter in healed pockets or sinuses, and thus more or less completely shut off from the circulation and tissue fluids of the body, and in support of this hypothesis he mentions the alleged superior efficacy of earlier treatment with ipecacuanha by oral administration. He has introduced a compound of emetine and bismuth iodide for oral administration, with which to obtain the advantages of the ipecacuanha and yet avoid its pharmacological action. He has reported promising results in cases treated with this double salt.

The presence of some cases of amoebic dysentery in No. 4 Canadian General Hospital provided an opportunity to study the action of emetine bismuthous iodide. The observations on which this report is based were made upon 6 cases, all known to be carriers of *Entamoeba histolytica* cysts. Of much additional interest is the fact that 4 of these cases had been previously subjected to a course of emetine hydrochloride—daily doses of 1 grain hypodermically for 10 or 12 successive days in this hospital, and notwithstanding this treatment continued to pass cysts in the faeces. The emetine bismuthous iodide was administered in doses of 3 grains on 12 successive nights. When given immediately after the light supper which the patients have at 7 P.M. its administration was always followed with nausea and in some cases vomiting. These undesirable symptoms were least in evidence when the patients received the drug with water at 10 P.M.

In the following protocols tabulated reports of the protozoological findings are given.

CASE 1.—Patient, aged 24, left England in October, 1915. In July, 1916, he was troubled with diarrhoea, which continued at intervals and finally caused his entrance to hospital in August. Received emetine, 1 grain hypodermically, from August 26th to 30th.

Table of Findings.

Date.	Type of stool.	<i>Ent. coli.</i>	<i>Ent. coli</i> cysts.	<i>Ent. hist.</i>	<i>Ent. hist.</i> cysts.	<i>Lamblia</i>	<i>Lamblia</i> cysts.	<i>Coccidia</i> .

\* E.B.I. nightly from Aug. 31 to Sept. 12. † No protozoa. 1 *Amoeba coli* and *Amoeba coli* cysts on various days, but no other protozoa.

CASE 2.—Patient in Gallipoli in April, 1915. In July became ill with dysentery and was sent to hospital, where he was treated with emetine. In May, 1916, when in Egypt, had an attack of dysentery, and was sent to a general hospital and treated with emetine. In July, 1916, was admitted to a general hospital in this area.

Table of Findings.

Date.	Type of stool.	<i>Ent. hist.</i>	<i>Ent. hist.</i> cysts.	
Aug. 8	Light brown, faecal and mucus.	+	+	{ Aug. 6 to 18: Treated with emetine 1 gr.

" 22 to Oct. 20	No protozoa found.			—

CASE 6.—Patient had no previous history of dysentery.

Table of Findings.

Date.	Type of stool.	<i>Ent. hist.</i>	<i>Ent. hist.</i> cysts.	
Sept. 25	—	+	—	{ E.B.I. commenced.
" 26	—	+	—	
" 27 to Oct. 20	No protozoa found.			—

As is shown in the preceding protocols, 5 of the cases ceased to pass *Entamoeba histolytica* in the active or encysted form 48 hours after the institution of treatment. The sixth case continued to pass cysts for six days, after which the microscopic findings were negative. These observations have a greater significance when it is remembered that 4 of the cases had previously received a course of emetine hydrochloride, despite which they continued to pass the entamoeba in its active or encysted stage. Our observations in these 6 cases confirm the results obtained by Dale<sup>1</sup> and subsequently by Low and Dobell.<sup>2</sup>

The drug was obtained, through the kindness of Lieutenant-Colonel Dudgeon, R.A.M.C., from the Medical Research Committee.

## SURFACE-TENSION AND THE WASSERMANN REACTION.

BY VINCENT B. NESFIELD, F.R.C.S. ENG., &c.,  
MAJOR, INDIAN MEDICAL SERVICE.

IN February, 1916, it occurred to me to test the bearing of surface-tension (S.T.) on the Wassermann reaction in view of the fact that S.T. plays an important rôle in adsorption phenomena. This inquiry naturally led on to a further one into the tension-lowering effect of alcohol, which is the main constituent of the antigens used in the test. The conclusions to which I came were as follows: 1. That S.T. is the all-important factor in the Wassermann reaction. 2. That alcohol, bile, carbolic acid, and solutions of cholesterolin, which act as antigens in the Wassermann test, all have very low S.T. and greatly reduce the S.T. of serum. 3. That it is difficult to distinguish a syphilitic antigen from a substance which lowers S.T.

These facts are capable of easy verification, but their explanation is a more difficult matter. The question suggests itself: Did Wassermann recognise the S.T. lowering action of alcohol? I think myself that he must have known but intentionally suppressed the knowledge because, the test being founded on the Bordet-Gengou reaction, few would have given credence to it if alcohol alone, or with the addition of  $\frac{1}{2}$  per cent. carbolic acid, had been used in place of a specific extract.

In this connexion the history of the test is informing. An extract of syphilitic liver was first used, one gramme of liver being extracted with carbolised saline. Then it was shown that normal liver was as efficient. In each of these cases the best fluid contained bile salts and carbolic acid. As it was found that these watery extracts were unstable, alcohol was added, and it was then discovered that almost any organ of any animal produced an excellent antigen, the reason obviously being that it is the alcohol itself which is the antigen.

*The test employed.*—For the purpose of my inquiry I followed Fleming's modification of the Wassermann test, previously sensitising the sheep's red blood corpuscles with haemolytic serum (Allen and Hanburys). The antigen I used as a control was an alcoholic extract of human heart 2 parts and 1 per cent. alcoholic solution of cholesterolin 1 part, the procedure being as follows:—

One volume of unheated serum was mixed with 4 volumes of a 1 in 20 dilution of antigen in saline. This was kept at 98° F. for 30 minutes, and then 1 volume of a 1 in 5 emulsion of the sensitised sheep's corpuscles was added and the tubes incubated again for one hour. 1 in 40 and 1 in 80 dilution of antigen were also used in each case so as to determine the degree of reaction. I put up precisely similar tubes, using 95 per cent. alcohol in dilutions of 1 in 20, 1 in 40, and 1 in 80 in place of the extract, and also 95 per cent. alcohol in the above dilutions, plus 1 volume  $\frac{1}{2}$  per cent. carbolic acid.

The serum used was from patients with typical syphilis, and the controls were known to be free from syphilis. The experiments were repeated again and again, always with the same result, and lead to the conclusion that 1 in 20 alcohol absorbs alexin from syphilitic serum and not from normal. 1 in 80 alcohol, plus 1 in 1000 carbolic acid, acts in the same way, so that carbolic acid, like cholesterolin, increases the antigen power of alcohol, while at the same time reducing the S.T.

*The instrument for measuring surface-tension.*—A simple definition of S.T. is the force which drives a fluid against gravity up a fine capillary tube. The only text-book methods which I could find for S.T. were based: either on a comparison of the height to which different fluids rise in capillary tubing of constant bore, or on the rate of flow of the different fluids under constant pressure through capillary tubing. Both these methods present practical difficulties, making them inaccurate in my hands and not sensitive enough for the purpose I had in view. It is obvious that the rise of a column of fluid up a very fine capillary tube exerts an easily measurable pressure. All that is necessary is to hold down the fluid with a column of air and measure the pressure required to do so. For this purpose I drew out a stout glass capillary to a fine point and dipped it in the fluid to be tested. The capillary was then connected by a rubber tube with a 4 oz. bottle half filled with water, and closed by a rubber cork with three perforations: one for the capillary connexion, one for a manometer,

and one communicating with a rubber ball by squeezing which a pressure could be set up. The manometer was a glass tube graduated in millimetres passing to the bottom of the bottle and, in order to make it more sensitive, bent at an angle of 45°, thus increasing the length of the column of water denoting a particular pressure. A typical experiment was conducted thus:—

The capillary point was made to dip in distilled water. The rubber ball was squeezed, and water from the bottle rose in the manometer to 800 mm. A clip was applied between the rubber ball and the bottle to maintain the pressure. Air bubbled out of the fine capillary opening through the distilled water, while the water level in the manometer gradually sank till the escape of air from the fine point ceased. The water in the manometer now stood at 700 mm. Absolute alcohol was now substituted for the distilled water. Bubbling at once recommenced, and the manometer sank to 70 mm. The S.T. can now be stated as the ratio between the manometer reading for water and the reading for alcohol.

The following liquids were also tested and found to possess low S.T.: ether, xylol, benzene, petrol, petroleum, peppermint oil, and nitric acid. Solutions of sodium chloride and sodium citrate in water raised the S.T. a little, while sodium salicylate (belonging to the carbolic group) reduced it.

A further useful application of this simple apparatus is that by estimating the S.T. of dilutions of alcohol, carbolic acid, &c., it provides an accurate method of determining the percentage composition of such solutions. The presence of sugar does not impair the accuracy of the determination which therein possesses a great advantage over the hydrometer.

I am informed that an apparatus on similar lines has been used in alcoholometry, but I have not seen it, nor read an account of it. I showed my apparatus to Colonel Sir W. Leishman, Colonel F. R. Ozzard, I.M.S., Major W. E. McKechnie, I.M.S., to all of whom it was a novelty, and I was under the impression at the time that I was the first to use this principle. I believe that it will have an important application in the detection of adulterations, and that it will become the rule to state the S.T. when describing a liquid or salt solution.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### NOTES OF A CASE OF TRAUMATIC HERNIA OF THE DIAPHRAGM PROVING FATAL SEVEN MONTHS AFTER THE WOUND.

BY C. P. SYMONDS, M.R.C.P. LOND.,  
TEMPORARY CAPTAIN, R.A.M.C.

ALTHOUGH in this case the rent in the diaphragm was so large that nothing could have been done to repair it, it is possible that such cases may occur again and that an earlier diagnosis might enable the surgeon to operate with some hope of permanent relief.

Private —, of the S.A.I., aged 29, was admitted to the Connaught Hospital on the afternoon of August 31st, 1916. He had had no previous illness and had led a vigorous and healthy life. In February, 1916, while fighting against the Senussi, he was hit when stooping forward, so that the bullet, entering over the left scapula, apparently came to rest in the subcutaneous tissues of the abdominal wall in the left hypochondrium. He was taken to a dressing station where he vomited some blood, and subsequently to a base hospital at which an operation was performed on his abdomen and he believed the bullet was removed. Both wounds were healed in ten days; he was kept in bed for five weeks, became restored to full health and was eventually discharged to duty.

About six weeks after the original wound he had his first attack of abdominal pain; it was very slight. Subsequently he had many such attacks, three or four a month; although more severe latterly he had not felt ill enough to report sick. The attacks were nearly always preceded by constipation; he then had a premonitory feeling of uneasiness in the abdomen, and if he could now get his bowels to open well could sometimes avert the attack. The pain came on after or half-way through a meal and would pass off in a few minutes, being

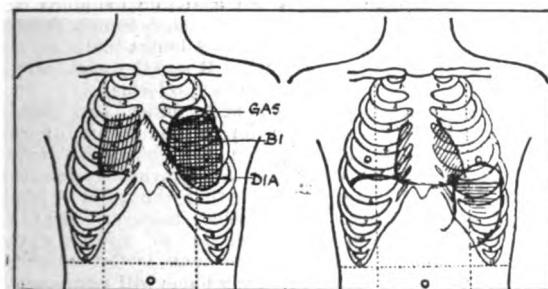

relieved when he lay on his right side; while it lasted it was very severe, but in between the attacks he felt quite well, though he thought his wind was not as good as it had been.

He was admitted in what he described as a typical attack, but much more severe than any before experienced. His bowels had not been open for two days, and then half-way through breakfast had come on the pain; he vomited the food just taken, but with no relief. On examination he proved to be a well-developed man of normal physique; over the centre of the spine of the left scapula was the scar of the entrance wound; in the middle of the left hypochondrium was a healed two-inch linear incision. He complained of a dull continuous pain across the upper abdomen, to which were added occasional paroxysms of agony, during which he turned pale and cold and broke out into a sweat, while his pulse was small, slow, and irregular. The position he adopted during these paroxysms was very striking, sitting bolt upright with his knees huddled up to his chin, the slightest attempt at straightening the back being intolerable.

On inspection and palpation the left hypochondrium appeared emptier and the left thorax fuller than on the other side. The physical signs in the chest resembled those of a hydropneumothorax. The right border of the heart was 2½ inches to the right of the sternum; the apex beat was not palpable, but was best heard in the fourth left space close to the sternal margin. At the apex of the left lung the percussion note was of a higher pitch than at the right, and the breathing was bronchial. But from the second space downwards the note was tympanitic all over the cardiac area and continuous with the stomach resonance. There were no breath sounds over this area, but with the patient in the sitting position curious tinkling sounds were audible in the third space. The signs at the back were similar, and bell sounds with coins were easily demonstrated.

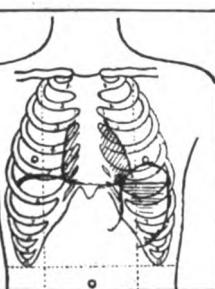

The true diagnosis did not strike me at the moment; I thought the dilated stomach was pushing up the diaphragm. But in a quiet interval between two paroxysms I gave the patient 3 ounces of bismuth carbonate, and with the help of Captain F. S. Hawks, radiographer to the hospital, examined him with the screen. The horizontal position was the only one available, but the picture obtained was quite definite. (Fig. 1.)

FIG. 1.

To illustrate X ray appearance on Aug. 31st. DIA, Diaphragm.

FIG. 2.

X ray appearance on Sept. 19th.

All the bismuth was contained in the stomach, which reached up to the second left rib in front, and above it could be seen the dense compressed lung. The time for observation was limited, for a paroxysm of pain compelled the patient to revert to the sitting position; but Captain Hawks was able to see a fine shadow to the left of the lower end of the stomach, having a slight vertical movement with respiration, which he took to be the diaphragm. The diagnosis of diaphragmatic hernia was now made. Most of the bismuth was removed by means of a stomach-tube and evacuator, but this gave no relief.

Two doses of gr. ¼ of morphia were given in the night and the patient had a little sleep still in the sitting posture, and as his general condition was better he was transferred early next morning to the care of the surgeons at the Cambridge Hospital. Here his condition rapidly improved, the pain disappeared, and in a few days he was able to take his food without discomfort.

Through the courtesy of the officer commanding the Cambridge Hospital and the officers in charge of the case I was able to see the patient again 19 days later. No operation had been performed and he was apparently in normal health. Physical examination showed the stomach resonance to reach the fourth rib, and the heart was a little displaced to the right. This was confirmed by X ray examination in the vertical position. (Fig. 2.) The left dome of the diaphragm showed as a clear, thin line, with no breach in its continuity; the stomach lay below it, and the picture

was apparently that of distension of this viscus with consequent stretching of the diaphragm. There can be no doubt, however, that the correct interpretation of this picture was that the surface area of the diaphragm was increased and its contractile power diminished by reason of the large gap in its substance which was subsequently discovered, and that the high position of the stomach with displacement of the heart was consequent upon this. There was now some debate as to the validity of the original diagnosis. Those who opposed it brought forward the argument that the bullet, if it had indeed passed through the diaphragm, must have damaged the scapula, of which a plate was produced showing no evidence of injury; moreover, that continuing its course it could hardly have failed to pierce the heart and so cause death. Subsequent events showed the fallacy in any argument based on the theoretical course of a modern bullet between wounds of entrance and exit.

A fortnight later the patient had another attack of abdominal pain; operation was performed and the hole in the diaphragm found, but his condition was desperate and he subsequently died of shock. At the post-mortem a large circular opening with quite smooth and rounded edges was found near the centre of the left dome of the diaphragm which would admit of a medium-sized hand being passed into the thorax, in which were contained the stomach, great omentum, transverse colon, and the upper half of the small intestine, the last being kinked in several places, distended, and of a deep plum colour. The stomach reached as high as the second rib and was partly adherent to the chest wall; the apex of the heart lay just to the left of the sternum. Finally, the expanded copper casing of a rifle bullet was discovered in one edge of the wound of the diaphragm, but no trace of the leaden core was found; presumably it was that which had been removed from the abdominal wall.

A remarkable point about this case is the length of the history. The wound in the diaphragm must have existed from the first, and apparently the increased intra-abdominal pressure resulting from constipation was the occasional cause needed to force a knuckle of stomach through the opening. The contractions in this knuckle set up by taking food then caused the agonising pain, partly relieved only by the crouching position, in which the tension of the diaphragm was reduced to its minimum. To this was added the continuous ache, probably due to the drag of the stomach and other viscera upon their peritoneal attachments. Up till the attack in which I first saw him spontaneous reduction must have occurred quite easily on every occasion, and eventually happened even after the stomach had been above the diaphragm for at least 24 hours. Of the symptoms when the patient was first seen, the most important features were the presence of gastric distension and abdominal pain without vomiting, the fact that the condition was not relieved by the passage of a stomach-tube, and especially the posture adopted.

I am indebted to Lieutenant-Colonel W. Turner, officer commanding the Connaught Hospital, for permission to publish this case.

Aldershot.

#### A NOTE ON THE BLOOD CHANGES IN GAS POISONING.

BY JAMES MILLER, M.D. EDIN., F.R.C.P. EDIN.,

CAPTAIN, R.A.M.C. (T.);

AND

HARRY RAINY, M.A., M.D. EDIN.,

CAPTAIN, R.A.M.C. (T.)

We venture to draw attention to a point which appears to be of some interest, and possibly of importance, which has recently come under our notice as the result of differential blood counts in cases of gas poisoning. We have not yet examined any very large number of cases, but we are extending our observations, and hope to publish them in detail at an early date. We have made inquiries and have looked up some of the literature—e.g., the Memorandum on Gas Poisoning in Warfare, with Notes on its Pathology and Treatment—and have failed to find any similar observation.

We append a table of a series of 14 cases taken at random, an analysis of which appears to bring out the following facts: 1. A case which has been gassed sufficiently severely to produce symptoms lasting for some time shows a more

or less marked relative lymphocytosis. 2. This change in the blood takes some time to develop. Probably three to four months at least must elapse before the change appears, but once it develops it does not disappear for some time, apparently for at least a year, if symptoms of any kind persist.

No.	Leucocyte count.	Poly-morphs.	Mono-nuclears.	Lympho-cytes.	Eosino-philes.	Mast cells.
	per c.m.m.	%	%	%	%	%
1	5703	50·2	4·6	40·8	3·4	0·8
2	—	53·19	5·5	40·0	0·4	0·8
3	5968	47·6	2·6	44·6	1·8	1·8
4	6570	33·5	3·7	60·0	1·0	0·7

13	5000	35·3	2·7	58·2	3·2	0·2
14	8122	47·9	2·4	47·6	0·3	1·5

Note.—The results represent an analysis of 300-500 leucocytes, and in several instances the counts were repeated on more than one occasion and by more than one observer.

#### Remarks.

1. Gassed June, 1916. Helmet was blown off, and he lay in a wounded condition exposed to gas-shell attack. Nausea the only after-symptom.
2. Gassed June, 1916. Marked symptoms. Discharged from Army as result (September, 1916).
3. Gassed September, 1915. Marked eye symptoms and tremors still present.
4. Gassed April, 1916. Fairly severe, cannot march any distance. Tremors.
5. Gassed Sept. 25th, 1915, very slight, did not report sick, no symptoms now.
6. Gassed September, 1915. Suffers still from eye symptoms and tremors.
7. Gassed July, 1916. Exposed for a short time, no symptoms.
8. Gassed September, 1915. Buried near a burst cylinder. Unconscious for four hours.
9. Gassed October, 1915. Exposed for 20 minutes, dazed, cough for three months.
10. Gassed September, 1915. Very slight, no after-effects.
11. Gassed December, 1915. Very slight, no after-effects.
12. Gassed July, 1916. Rendered unconscious, suffers from cough, tightness in chest.
13. Gassed April, 1915. In hospital at the time. Hospital blown up. Unconscious for a few hours. Cough, shortness of breath, and nausea.
14. Gassed September, 1915. Unconscious for four days. Intense nausea, and vomiting for several days. No cough.

We are not able to state whether this sign is present in all types of gas poisoning or only in certain of them, because it is a difficult matter to obtain any definite information on this point from the patient himself. As regards the number of the leucocytes per cubic millimetre there does not appear to be any marked change, if anything there is a slight reduction.

Dr. H. Fielden Briggs has been elected by the dental practitioners of the Transvaal to represent them upon the Transvaal Medical Council.

THE LATE DR. P. G. BORROWMAN.—In Philip Grierson Borrowman, who died at the age of 62 on Dec. 17th last after a short illness, the profession in Edinburgh has lost a much respected member. Though subjected during much of his professional life to the restrictions of ill-health, Dr. Borrowman had a large and varied experience of medical work in many spheres, having practised in Earlston, Colombo, Elie, Crieff, Troon, and latterly, for six years, in Edinburgh. He also found time to make a number of short practical contributions to medical journals. In his later years in Edinburgh his health improved considerably, and in addition to his practice he has had recently the satisfaction of taking work for younger men who have gone abroad and of doing a certain amount of war service of various kinds, besides holding the post of surgeon to the mounted constables. He has left a widow, two sons, and a daughter. Of his sons one is a minister of the Church of Scotland, the younger is an officer in the Indian Army; both are on active service.

## Reviews and Notices of Books.

### Medical Diseases of the War.

By ARTHUR F. HURST, M.A., M.D.Oxon., F.R.C.P.Lond., Temporary Major, R.A.M.C.; Physician and Neurologist to Guy's Hospital; Neurologist to the 3rd Southern General Hospital; lately Member of the Medical Advisory Committee, Mediterranean Expeditionary Force, and Consulting Physician to the Salonica Army. London: Edward Arnold. 1917. Pp. 151. Price 6s.

THIS is an opportune and admirable book.

The first of the ten chapters is on functional nervous disorders, and contains an interesting account of shell shock. Some stress is laid on the initial minute changes in the central nervous system as forming the organic basis for the symptoms which persist and become exaggerated from psychical causes. No definite line can be drawn between cases with obviously organic symptoms and those with obviously hysterical manifestations due to auto-suggestion, and many intermediate cases occur. For the hysterical symptoms hypnotism is eminently successful, and everyone in charge of the neuroses of soldiers should be capable of carrying out this method of treatment. In Chapter II. the various forms of dysentery are clearly described. With regard to the presence of *Lambia intestinalis* in the stools it appears that importance should be attached to them only when there are concomitant symptoms. It is remarkable how few cases of amebic hepatitis and hepatic abscess have been recognised. In patients with bacillary dysentery who have previously had antitoxic serum for other diseases, or who suffer from asthma, the danger of anaphylaxis can be obviated by subcutaneous injection of 1/10 c.c. of the multivalent serum before intramuscular injection of 20 c.c. of the serum. In ordinary cases the serum is given intravenously so as to ensure the most rapid neutralisation of toxins by the antibodies. War nephritis and both forms of trench fever were seen at Salonica, where the available evidence confirmed the opinion formed in France that trench fever is spread by lice. It was not possible at Salonica to distinguish clinically between paratyphoid A and B, and there was no real difference between the severity of the two forms.

Epidemic jaundice is dealt with under two heads: (1) Among the Mediterranean forces, due to an infective duodenitis; (2) in France, due to *Spirocheta ictero-hæmorrhagica*; as this disease was previously described by the French the author urges that the term "Weil's disease" should lapse. In practice, however, the title *spirochætosis ictero-hæmorrhagica* is so unwieldy that unless some shorter and distinctive name is forthcoming it seems to us unlikely that the enemy name will permanently fall out of use. It is also, perhaps, open to question if all the cases of jaundice on the Western front were of the same nature, especially as the mortality (6 per cent.) was so much lower than that of spirochetal jaundice in Japan and Egypt (30 per cent.). Dr. Hurst considers that beri-beri as seen at Gallipoli was due to a duodenal infection, similar to that described in 1905 by Hamilton Wright, and that though the anti-beri-beri vitamine was probably a contributory factor it was not the sole cause. It is significant how frequently this form of peripheral neuritis followed jaundice, and an apt comparison is drawn between this sequence and that of diphtheria and paralysis.

Under the etiology of the soldiers' heart the claims of intoxications, over-exertion, and nervous strain are clearly discussed; and in regard to the first it is pointed out that as over-activity of the thyroid is more easily detected than that of the other ductless glands, this form of cardiac disease has been called hyperthyroidism, but that there is really a disturbed activity of all the ductless glands. In this form of soldier's heart, due to a "vegetative neurosis," the blood pressure is raised, in contrast to its low level in the other forms, and this is regarded as evidence against simple hyperthyroidism, the author stating that in uncomplicated Graves's disease the blood pressure is not raised—a conclusion on which there is, perhaps, room for discussion.

The sections on the various diseases are well written, are in due proportion to their interest and importance, and should ensure a second edition at an early date, when perhaps some further chapters might be added.

*The Treatment of Infantile Paralysis.*

By ROBERT W. LOVETT, M.D., Boston. London : William Heinemann. 1916. Pp. 163. Price 8s. 6d.

As the title of the work indicates, it deals chiefly with the treatment of the affection, but there is a short introductory chapter on the pathology, symptoms, types, mortality, diagnosis, and prognosis of the disease. With regard to the mortality, it is interesting to note that in no instance did it reach the high percentage recorded in the American epidemic of 1916. The author asserts that complete recovery without atrophy occurs more frequently than is generally thought, and quotes figures from the Massachusetts epidemic showing that it amounted to 27 per cent.

The treatment is described in four chapters, that of the acute phase, the convalescent phase, the chronic phase, and operative treatment. In regard to the acute phase, the author sums up the treatment with these words, "Rest until the tenderness has disappeared, absence of meddlesome therapeutics, either medicinal or physical, the use of warm baths in the later part of the period, and the prevention of contraction." The treatment during the convalescent phase consists in teaching the patient to walk, the prevention of deformity by the use of instruments, and the application of massage, heat, electricity, and muscle training. To this latter the author devotes a special chapter, giving detailed instructions of the position in which the limb should be placed in order to bring into action individual muscles. This is probably the most important chapter in the book, and the author acknowledges the aid he has received from his assistant, Miss Wright, in this matter. The numerous deformities liable to occur during the course of the disease are described and figured, and the various methods, both instrumental and operative, are discussed. The final chapter deals with "muscle test," a test by which under conditions of constant position and leverage, by a series of spring balance pulls, the power of the muscles which govern the movements of the limbs can be registered.

The book is well illustrated with photographs and diagrams of the procedures for dealing with the many conditions of muscular weakness and deformity caused by poliomyelitis.

*Medical and Veterinary Entomology.*

A Text-book for Use in Schools and Colleges, as well as a Handbook for the Use of Physicians, Veterinarians, and Public Health Officials. By WILLIAM B. HERMS, Professor of Parasitology in the University of California. New York : The Macmillan Company. With 228 illustrations. Pp. 393. Price 17s. net.

THE author of this book has done good service in bringing under one cover the widely scattered literature of medical and veterinary entomology. He has not rushed into print, for he states that he has spent six years in gathering information and making investigations and observations in this special field. The result appears to justify his labours. The subject-matter is well arranged; the illustrations, many of which are original, are apt and good, and the whole field of prevention of disease due to insects is effectively covered. We think the author is at his best in the chapters on mosquitoes, the common house-fly, and the control of rats and rat-fleas. He describes the extermination of bubonic plague in the city of San Francisco by measures dealing with the last-named pest. He regards the cockroach as a possible carrier of tuberculosis, dysentery, cholera, and typhoid fever. The life-history and habitat of the various pests are dealt with in chapters on cockroaches, beetles, lice, bugs, mosquitoes, house-flies, blood-sucking mscids, flesh flies, fleas, ticks, and mites, and the book concludes with an interesting chapter on venomous insects and arachnids. It will form a welcome addition to the library of the sanitarian and epidemiologist.

## LIBRARY TABLE.

*Paton's List of Schools and Tutors, 1917.* London : J. and J. Paton. Pp. 999. Price 2s.—This is the nineteenth annual issue of a thoroughly useful publication and does not differ in arrangement from the immediately preceding issues. We have, first, a classified list of schools, comprising an index of preparatory and other schools for boys and girls in the three divisions of the United Kingdom. Lists are also given of prizes and scholarships at the various

schools, as well as of special schools and training colleges for technical instruction. Where possible, full information in respect of fees is appended. Useful little essays will also be found on the education necessary to obtain Civil Service appointments, military and naval commissions, and commissions in the mercantile marine, while the portals of the professions of architecture and medicine are examined. The essay on the entrance to the medical profession is a particularly sensible one; it gives to the lay parent the necessary information in a popular form.

*The Passing On of Life: A Talk about Ourselves.* By the Viscountess FALMOUTH. London : George Routledge and Sons, Limited. 1916. Price 1d.—This tract on the reproduction of the human species is a section of the author's "Talks about Ourselves: Simple Teaching in Hygiene and Physiology," which has been extracted from the book and enlarged to make its message clearer. It is a complete estimate of the pamphlet to say that on a very difficult and delicate subject the message is perfectly clear. Lady Falmouth follows lines that have been followed before, in preparing the minds of the juvenile readers for whom she writes, when she begins by an explanation of plant fertilisation. A sketch of bird life follows and introduces us to cattle-breeding and its eugenic theories, before the sex question as it affects the human race is actually touched upon. Here, taken with all that has preceded, quite enough is taught, and the religious tone of the passages which inculcate the value of self-restraint and the influence of right thinking is impressive in its direct simplicity. The dissemination of this unpretentious tract should be very valuable, especially at a time when the absence by over-employment of many parents makes the up-bringing of children difficult if they are to be kept in the right way.

*The Greek Tradition: Essays in the Reconstruction of Ancient Thought.* By J. A. K. THOMSON, M.A. London : George Allen and Unwin, Limited. Pp. 247. Price 5s. net.—Mr. Thomson's book is a further development of his Studies in the *Odyssey*, and will be a revelation to all whose acquaintance with the classics has been in the nature of a mechanical task or a form of educational gymnastics. Not merely do the characters live, but the author's lively and instructed imagination has reconstructed a background of contemporary colour which makes the whole topical. We commend the book to all those to whom ancient Greece has hitherto been a sealed book.

## MISCELLANEOUS VOLUMES.

A SERIES of handbooks is now being issued, under the common title of Mind and Health Series (London : William Heinemann. Price 5s. net each). The wish of the editor, Mr. H. Addington Bruce, is to extend a popular knowledge of such developments of psychological research as bear more obviously upon social and individual welfare. The first four volumes deal with the investigation of what is known as the "subconscious territory of the human mind," an attempt being made to explain the way in which mental processes are carried on behind or beneath consciousness, and to estimate how far these processes affect what is generally termed the character of the individual, as illustrated by motives and behaviour. A whole literature of a quasi-scientific or quasi-medical character has grown up of recent years in this direction, but these small volumes are intended rather as a recognition of the demand made by teachers, parents, and other responsible citizens for instruction.

The opening volume, "Human Motives," has been written by Professor James Jackson Putnam, emeritus professor of diseases of the nervous system at Harvard University and a highly esteemed worker in the field of medical psychology; it has a more general character than the other volumes of the series so far issued. The attempt is made within a very brief compass to erect a practical philosophy of life for the assistance of the teaching of modern psychology. Finding in nature two sets of motives behind action—namely, those promoted by love of humanity and freedom, and those unconsciously entertained, being legacies from forgotten portions of life and experience—Professor Putnam urges that real self-knowledge must follow the discovery of how much the first set of motives are influenced by the second. From a description of the main sources of motives he passes naturally to consider not only the bearings of psycho-neuroses and the development of consciousness, but also religion, when regarded as a standard of motives.

He presents the reasons why an industrious psychological worker finds his religious convictions to have been strengthened by his experience.

In the second volume of the series, "The Meaning of Dreams," Dr. Isador H. Coriat, assistant physician for nervous diseases to the Boston City Hospital, surveys the principles of dream-analysis along the lines formulated by Freud. Freud's work in this direction he describes as one of the greatest advances ever made in the knowledge of human mind and human motive. The examples of dream-analysis contained in the book follow methods well known to our readers, who will not with any unanimity be prepared to endorse the views expressed. The general editor of the series is on safer ground in "Sleep and Sleeplessness," wherein the various theories of sleep are exposed, prominence being given to recent experimental studies in the attempt to illustrate the causes and treatment of sleeplessness, as well as to discuss the apparent relationship of dreams with what is called the "supernatural." The theories quoted are not all of equal scientific standing, nor will all the stories emerge with equal credit from minute examination, but this is a very interesting little book. Dr. Dearborn strikes new ground in the fourth essay, "The Influence of Joy," which purports to be an account of modern methods of research into the specific effects of joy and other emotions. "The scientific economics of joy and happiness"—this is exactly what he writes—"remains to be developed, and our thesis insists that it is developable. In other terms, joy has an evaluation (even if not yet in figures) in State Street on the bulletins of the Stock Exchange; in the concrete-and-glass factory of Mr. Shoemaker; among the maids in your home; in the coal-mine; aboard ship; in your own private accounts which you keep to satisfy the income-tax collector. Daily joy has money value as well as soul value, even in the manual trades. And soon some man (or, more likely perhaps, some ingenious woman economist) will begin to reduce it to grades, to 'standardise' it and to find its mean financial value to all sorts and conditions of workers." We learn from this book the close connexion between happiness, or at any rate content, and high working efficiency, but it is doubtful whether a treatise required to be written in order to prove that the emotions of happiness stimulate the bodily functions and cause thereby a more satisfactory output of effort with correspondingly good results.

All these books are laudable in their endeavour to make the public free of information in directions where its supply might lead to an improvement of morals, or the erection of needed standards of conduct. Further, if the teaching is often sketchy and the meaning of the authors thereby obscured, we must remember the difficulties of the attempt to translate into simple terms the conclusions of complicated thinking. But there is no note taken of the difference between scientific literature and pretentious jargon, or between real and imitation scientific procedure, so that questions that perplex many thoughtful persons remain without trustworthy answer. To cite Sigmund Freud's revolting work is not to enunciate the accepted truth, even if the German psychologist is not so wholly obsessed by sex questions as he appears to be; and some of the other writers quoted as authorities can have no authority whatever.

Dr. R. W. MacKenna's book (*The Adventure of Death*) London: John Murray, 1916 Pp. 168 Price 3s. 6d. net) covers certain extent ground that passed over by the volumes in the Mind and Health Series. He has considered the subject of death from different points of view, not necessarily the obvious ones, and the result is an essay of a really inspiriting sort. Fear he finds to be absent from most death-beds, and pain to be quite unusual at the end, however bitterly it may have accompanied the earlier stages of some diseases. A short chapter enumerating what life gains from death exemplifies well the words of Robert Browning, which are quoted by the author in this connexion:—

You never know what life means till you die.  
Even throughout life, 'tis death that makes life live,  
Gives it whatever the significance.

Dr. MacKenna utterly discredits the materialistic school, and finds on every side that man is more than matter and that personality survives the grave. At a time like this, when millions are facing sudden death daily, and when their parents and wives, children and friends, are filled with apprehension of their fate, this fine little essay may prove a consolation with a wide message.

## Reports and Analytical Records FROM THE LANCET LABORATORY.

### EUCALYPTOL (CINEOL).

(HUDSON'S EUMENTHOL CHEMICAL COMPANY, LIMITED, SYDNEY, AUSTRALIA. LONDON AGENCY: F. NEWBERY AND SONS, LIMITED, 27 AND 28, CHARTERHOUSE-SQUARE, LONDON, E.C.)

AN examination of this brilliantly clear colourless oil gave indications of a very high eucalyptol or real cineol content. Thus its specific gravity was found to be 0.9295, whereas the oils showing a small proportion of cineol have a decidedly lower density. In fact, we have not examined a eucalyptus oil showing a higher density than is here recorded. We understand that the oil has been prepared by a freezing separation method. We found that its boiling point lay between 165 and 170° C. There were just traces of moisture present. An oil showing these constants should be well adapted for medicinal purposes. It is free from irritating constituents such as aldehydes and can be inhaled without causing coughing. It is noteworthy that eucalyptus on oxidising in contact with the air produces a fair amount of ozone.

### "SMALL TEA."

(BROOKE BOND AND CO., LIMITED, GOULSTON-STREET, ALDGATE, LONDON, E.)

We have already reported in these columns upon a sample of what is called "small tea," which is stated to consist only of the fine part of the leaf edge. On analysis a five minutes' infusion of this tea showed a proportion of caffeine to tannin of 1 to 3 (caffeine 2.7 per cent., and tannin 8.0 per cent.), and when this result is obtained by chemical analysis the tea proves invariably to be of a good dietetic character, free from excess of tannin and from excess of caffeine. The alkaloid, in fact, is presented in the form of a neutral tannate. We have received a further sample which is described as being of a still higher quality. We found that it produced an infusion (five minutes) smooth, soft, and delicate to the palate, and, again, analysis showed that the caffeine was present in the proportion of 1 to 3 of tannin. The conclusion seems to be confirmed that harsh, astringent or bitter teas owe their properties to, on the one hand, an excess of tannin present, or, on the other, to an excess of caffeine. The ratio is correct in the tea under examination, showing that in a five minutes' infusion caffeine-tannate is extracted, but neither free tannin nor caffeine. The result is a beverage that does not disturb the digestion.

### "SOOLID" NASO-PHARYNGEAL (EUCAINE) COMPOUND.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

This soloid is useful in the treatment, by a gargle or spray, of irritable conditions of the nose and throat. It contains, amongst other things, well-known antiseptic essential oils besides boric acid and sodium benzoate. The formula has been recently modified by replacing cocaine salt with eucaine hydrochloride. For the treatment of the nose and throat one soloid is dissolved in three ounces of water. A solution of two soloids in ten ounces of water has been found very useful as a lotion in conjunctivitis.

### "DIAL-CIBA."

(THE SACCHARIN CORPORATION, LIMITED, 36 AND 37, QUEEN-STREET, LONDON, E.C.)

The above is the short name given to an important barbituric acid derivative. It is, in fact, di-allyl barbituric acid or di-allyl malonyl urea. The ethyl group in veronal is replaced by the allyl group; this is said to give it important advantages. Thus whilst a powerful hypnotic, it is held to be less toxic and to produce no unpleasant after-effects. An interesting point in regard to its administration is that whereas diethyl barbituric acid is recoverable to a large extent from the urine as such, di-allyl barbituric acid breaks down into simpler bodies. These are important claims, and the new derivative is worth some attention. It furnishes an interesting example of the relation of chemical constitution to pharmacological action.

# THE LANCET.

LONDON: SATURDAY, JANUARY 6, 1917.

## An Ideal for the New Year.

THE New Year finds the medical man bearing his share of the war burden—a burden not exactly comparable to that borne by his fellow citizens. To every other man of military age, with but trifling exceptions, the call has come to train himself either to fight or to keep the fighting machine in full efficiency, his previous occupation having not necessarily been in any relation whatever to his new obligations. The call to arms takes little or no account of any man's particular talent or equipment, and, except in the case of the few who have obtained special duties because of their special aptitudes, there has been small attempt to make the military employment fit the civilian training. But the medical man has the privilege of being called upon by the State to serve his country by the exercise of the science and art in which he has been brought up; and, speaking generally, he can do this without further special education. Again, inasmuch as the State cannot afford to dispense with our normal activities for the public health, the medical profession is submitted not to the ordinary lay tribunal, but to the jurisdiction of a medical committee, who can appreciate the difficulties of the position and the force of any claims to exemption upon professional grounds. The medical man in time of war is doing for his country his own work and doing it in his own way.

But this work cannot be done without sacrifice and without hardship. The supreme sacrifice which a man can make has been made week by week by the officers of the Royal Army Medical Corps in company with their stretcher-bearers, as our pages and the war records of the different medical schools testify. But a sacrifice less dramatic than the loss of life, but in a sense hardly less complete, is daily being made by the doctor who gives up his professional life at the call of his country; he resigns all that the patient toil of his early years of practice has built up for him, and he does this with no chance of real security that he will be able to take up later what he lays down. Arrangements have indeed been made in many localities, good in themselves and more or less complete or incomplete; but at the best nothing can safeguard a position which depends upon personal interest and upon qualities of disposition and character, when these factors of success are removed from the scene. This sacrifice, which has been made by a large series of medical men since the outbreak of war, has been embittered in some cases by the feeling, right or wrong, that those remaining behind

have made capital or derived gain at the expense of the men who went. That absolute gain has been acquired comparable in any way to the vast profits which certain other sections of the community have been deriving from the war it is impossible to contend. But just as among the individual fighting units the contrast is a crying one between the man in the trenches exposed to hourly danger and terror, and his companion in the munition works living in comfort and safety under the admirable hygiene provided by a careful Government department, and earning enough to keep him in relative luxury—so in the medical profession there is the same contrast between the man who goes to the war and the man who stays behind. The latter is in every case the relative gainer in material things, and the knowledge is galling to all; for very many medical men who for public or private reasons of the most valid sort are remaining at their civil posts long ardently to share the harsher fate of their brethren.

One way only offers by which the inequality can be brought level. Identity of sacrifice for us all is an ideal which cannot be brought about by administrative action, but only by the willing co-operation of each member of a free society. The medical profession is a noble calling. If every member of the profession should now willingly and of his own initiative forgo any absolute war advantage, and, more than that, should try to arrange his life so that he gains no relative advantage over those who have joined the Navy or Army, this high estimate of our calling will be fully justified in the public eye. The reduction of his standard of living to something the level of that of his compeers at the front; the decision to make his work his best possible contribution, in the first instance to national service, and in the second to the welfare of his own profession: these measures will afford a solution to the problems which beset the situation, and which appear to divide the interests of the civilian medical service of the country from those of their brethren with the colours. No complete mobilisation of the medical profession will have been effected, whatever regulations are made, unless the idea of identical sacrifice is kept before us, and that is the level to which all should strive to rise.

## The Liquor Traffic and the Food Question.

THE increasing seriousness of the food problem in this country has raised afresh and in a more urgent form the question of the control of the liquor traffic in the interest of national efficiency. The advocates of more rigorous measures in restraint of drinking are now able to reinforce the arguments which they have been wont to base on the detrimental influence of alcoholic excess, by the further argument that the loss of energy-value involved in the conversion of the carbohydrate of grain and sugar into alcohol

represents in itself a serious leakage in our food-supplies, and one that should not be tolerated in a time of threatened shortage. There is, no doubt, a great deal of force in this argument, even though it may be rather less than is represented by some; and no one who examines the facts with an unbiassed mind will be concerned to deny that there is need of further restrictions on the manufacture and consumption of alcoholic beverages in this country. The only question about which there will be any difference of opinion is whether the policy to be pursued should be simply one of restriction, tentative and modifiable according to altering conditions, or whether recourse should be had at once to the drastic method of absolute prohibition of the sale of alcoholic liquors.

The policy of total prohibition has been very strenuously urged on the public attention of late, not only by recognised supporters of the extreme temperance position, but also by many business men and employers of labour, who, while not committed to any doctrinaire views on the alcohol question, are disposed to regard enforced teetotalism as desirable during the term of the war, both on grounds of food economy and as a salutary discipline. The arguments adduced in support of this policy are sufficiently cogent, and the influence and standing of its advocates sufficiently important, to ensure its respectful consideration; and it has moreover an attractive air of thoroughness and simplicity which can hardly fail to recommend it at a time when these qualities are held in such particular esteem. But, despite these recommendations, it may be questioned whether its results in actual practice would be entirely satisfactory—perhaps no one thinks that they would. It is tolerably certain that the enforcement of prohibition would be far from easy. And the difficulties might not be matters merely of popular emotion. One of the many points regarding the action of alcohol that might have been, but was not, studied in the days of peace is the effect on muscular and nervous energy when the habitual use of the drug is suddenly discontinued. Probably discontinuance has no detrimental effect, or at all events none of more than slight and transitory character; but, on the other hand, it is at least conceivable that men who for years have been accustomed to taking some form of alcoholic beverage as part of their diet after a hard day's labour, may be affected by its sudden and complete withdrawal. At the present moment several of the most vitally important industries in the country are relying very largely on the services of older and less robust men—men who have grown up in the use of alcohol; here a relatively small saving in food material would be dearly paid for by lessened activity. Allowance must be made in any regulations for the cases of those in whom abstinence produces ill-effects. There are other difficulties which the policy of prohibition would involve, and these are not remote as the case of those who suffer physically from abstinence may appear to be. Foremost amongst these is the

probable development of an illicit traffic in alcohol and in substitutes for alcohol which may be still more detrimental to public health and order. The experience of Russia during the present war is eloquent on this point. In that country the complete and abrupt prohibition of the sale of vodka—practically the only alcoholic beverage in popular use—while it undoubtedly has had excellent results in many directions, has at the same time produced a very serious extension of secret drinking, especially where an excess of local zeal has also prohibited the sale of other and less objectionable alcoholic liquors. Methylated spirit, varnish, and lacquer are amongst the substitutes for vodka which are stated to have been used, and the resulting cases of death or of complete or partial blindness have been extremely numerous. This evil would not be likely to attain to grave development in the case of our own population, but we know enough to see that it must not be ignored. And in this connexion it is, perhaps, significant that in Germany, though the food difficulty has long since reached a degree of urgency, it has not been judged necessary or expedient to adopt the policy of prohibiting the sale of beer, though the supply of materials to the brewer is already under limitation.

The alternative to prohibition is to impose restrictions on the consumption of ardent liquors, and to diminish also the amount of grain and sugar used in their production. The work of the Liquor Control Board has shown how much can be done in both these directions; the effect of their regulations in decreasing drunkenness and alcoholic disease, as measured by the most characteristic manifestation of alcoholism, delirium tremens, has been generally ascribed to the influence of the restricted hours during which public-houses may be opened, and this is unquestionably the main factor in the result; but it is probable that an important part has also been played by the action of the Board in enforcing the dilution of spirits, and in endeavouring to create a popular taste for a very low gravity beer. Apart from its beneficial influence on the public health, the introduction of weaker beers will, of course, involve a considerable saving in the use of food substances; it has been estimated that an all-round reduction of the specific gravity by 10 degrees would decrease the quantity of materials used by close on 20 per cent. Combined with further limitations on the amounts of beer and spirits to be released for consumption, a reform on these lines would go some way to meet the argument for prohibition which has been based on the present need for economy in the use of foodstuffs. Of course, such a policy would have to be general in its application, and, as a large elasticity in adjustment to varying conditions is of its essence, it could hardly be carried out except by a central organisation entirely untrammelled by considerations of trading interest. The most effective way in which these requirements can be fulfilled is obviously under a system of State ownership, and we are glad to note that the immediate establishment

of such a system has apparently been decided upon by the new Government, presumably on the lines adumbrated by Mr. LLOYD GEORGE when he urged the adoption of this policy in the early part of last year. State purchase has long been recognised by all social reformers of reasonable views as a practicable solution of many of the evils of the drink traffic.

### Welfare Work in Factories.

THE Welfare Department of the Ministry of Munitions carries out the recommendations of the Health of Munition Workers Committee. With these recommendations we have dealt as they appeared. The primary concern, naturally, of most departments of the Ministry of Munitions is output, which blossoms freely under an official routine, but welfare work is a tender plant which grows by kindness and suasion and withers in an atmosphere of official compulsion. Its chief sphere of action at the present time is to deal with the conditions of life generally among vast numbers of young women introduced—pitchforked one may almost say—by the acute need of labour into the engineering industry. The material of which the worker in munitions is composed, referring now to the female workers, has peculiar attributes and needs special treatment. The treatment is placed in the hands of a welfare supervisor, and the difficulty begins with the choice of a suitable person. It is no good for a welfare supervisor to be a sort of superior fore-woman. This only produces envy and irritation. She must manage the employees through her superior knowledge of life and have the quiet authority of position, while actually being willing to minister to their smallest needs. The ideal combination is probably that of supervisor with first-aid nurse. Where large numbers of young women are employed a constant stream of small distempers and accidents find their way out of the workroom. If referred to the male foreman the operatives will necessarily be excused and sent home, with harm to themselves and their work, inasmuch as a series of delicate operations may be checked for the day by the loss of a worker, and the girl herself loses her good record for punctual attendance and has a passing ailment magnified into a day's illness. Referred, on the other hand, to the welfare supervisor for advice and encouragement, the girl may be able, without harm, to return to her work after a short time of rest. The supervisor has at the same time gained her confidence, making the operative feel that she is an individual in whom personal interest is taken, while with this reputation among her charges the supervisor can soon do anything she pleases with them. Here is a field of immeasurable usefulness for the educated woman of leisure and tact, whether she has been recently trained in social work or has passed the age of family cares whilst retaining the motherly instinct necessary. It is social work at the fountain head.

What is the clear result to-day of properly conducted welfare work among female operatives? Not merely that the female operative

can give nine hours' work, exclusive of meal times, day or night without obvious harm; but that such work done under fitting conditions may result in an improvement of the physique of the town-dweller which will spell permanent benefit to the race. The woman munition-worker is in the direct road to become healthy, clean, and well-mannered. The health is due to the well-ventilated atmosphere in which she now works, to the good meals at regular hours with proper intervals of rest and recreation. In addition to all this her physique is in no little degree benefitted by keenness on the work which is often attractive in itself, for metal turnings are beautiful. Health and keenness react the one on the other. Cleanliness is at first a matter of industrial necessity; overalls and caps must be worn to protect flying garments and hair from the risk of catching in machinery; hot water and carbolic soap, followed by a suitable unguent, are enjoined to avoid dermatitis from handling irritating substances. But these practices lead to a love of cleanliness for its own sake and to the observation that a clean, washable uniform is becoming. Improvement of manners commences as an official necessity; larking is dangerous and has to be forbidden on account of its danger. But the growing interest in the work and in other subjects which a welfare supervisor can tactfully suggest ends by taking the place of any desire for practical joking, as well as of the grumbling at food which is, in all ranks of society, largely a question of mental unoccupation.

In the light of these results we must revise the accepted notions upon the effect of prolonged labour on the health of women workers. In the engineering industry the efficiency of female labour is a discovery, and although in certain large factories up and down the country welfare work has been carried out as a routine for 20 years or more its effects have not been duly appraised. We must now recognise much factory employment as a healthy occupation for young women under proper conditions of atmosphere, rest, nutrition, and personal care, and this is a matter of first-class medical significance. The bad effect of industry on female health was owing to the fact that the surroundings were bad, and although this was quite well known to medical men, and admitted to some extent in the labour world, the public did not accept the facts. They did not believe that the work was largely good in itself, though the conditions under which it was done were often not good. The present experience seems to show that a large proportion of women can, without harm to their work or themselves, continue at it throughout the whole time of their physiological cycle, without requiring more than a little personal consideration of a kind which the welfare supervisor can impose. The moral, which will sometime become a pressing one, is that wholesome industrial conditions are the reasonable demand of workers—women as well as men—in peace as in war, and it will become a charge upon medical men to see that these conditions are forthcoming.

## Annotations.

"Ne quid nimis."

### THE GOVERNMENT LABORATORY AND THE WAR.

As might have been expected, the war has placed considerable pressure upon the time and energies of the Government laboratory officials, and this is well shown in the report for the year ended March 31st, 1916, of the Government chemist, Sir James J. Dobbie, which was issued last week. The samples of food examined in connexion with the supply of the Expeditionary Force alone numbered 8901, as compared with 1348 recorded in the previous report. The greater part of the work of the department is carried out at Clement's Inn and in the branch laboratory at the Custom House. Six of the branch stations for testing for revenue work have been closed temporarily during the war, but the total number of samples examined from all departments was 383,892. There was a large increase in the number of samples of export tobacco examined due to the despatch of tobacco for the use of the British Expeditionary Force. The number of certificates issued in connexion with these samples was 81,889, an increase of no less than 48,179 over the corresponding period of last year. The food-supplies examined for the War Department included Army biscuits, flour, bread, pearl-barley, oatmeal, arrowroot, sago, and tapioca, desiccated potatoes and other vegetables, condensed and fresh milk, cocoa, jam, and meat extracts and essences, pepper, calf's-foot jelly powders, mustard, hops, malt, and beer, tinned meats and fish, soup powders, butter, sugar, and cheese. Tender samples were examined as to conformity with the specification, and bulk deliveries to ascertain whether they compared satisfactorily with the selected tender samples. In this direction more than 6000 samples were taken from contractors' deliveries in course of transit to the Expeditionary Forces. This system of control has, no doubt, effected considerable economies. The work now carried out at the Government laboratories is of great service to the nation and is of a much more comprehensive character than it was in the old time, when the Somerset House laboratories were practically exclusively devoted to questions of revenue and excise.

### STAPHYLOCOCCIC MENINGITIS.

AN interesting case of cerebro-spinal meningitis due to the *Staphylococcus pyogenes albus* is reported in the *Archives de Médecine et Pharmacie Navale*s for September by Dr. H. Bourges, médecin de 1<sup>e</sup> classe (staff-surgeon) in the French Navy. This case had a happier ending than most, for all the other similar cases quoted from the literature proved fatal, and Dr. Bourges ascribes the recovery of this patient to an artificial abscess he provoked by the method of Fochier—i.e., by the subcutaneous injection of sterile turpentine. The patient, a sailor, was suddenly attacked on Dec. 10th, 1913, when on sentry duty, with violent frontal headache, pains along the spine, weakness, and vomiting; his temperature was 103° F. When he reached hospital on the 11th a lumbar puncture removed 30 c.c. of fluid, and 20 c.c. of antimeningococcus serum was injected. As this injection produced no benefit it was never repeated. The fluid withdrawn contained

no meningococci, only Gram-positive cocci and diplococci. On the 12th lumbar puncture was repeated and the patient began to improve, but on the 18th he relapsed, with severe frontal headache, pain along the spine, stiff neck, temperature 104°, but pulse only 80, insomnia, and daily loss of weight. He was having ice to his head and a warm bath every four hours, a collargol enema, and daily intravenous injections of electrargol. The sputum was examined for tubercle bacilli and pneumococci without result, but from the fluid of a third lumbar puncture the *Staphylococcus pyogenes albus* was grown. The temperature continued steadily at the same high level, the general condition persisted, and a fourth lumbar puncture on Dec. 29th showed that the cerebro-spinal fluid was purulent, the cells mainly polymorphonuclears, and it was decided to provoke a fixation abscess by the method of Fochier. Accordingly 1 c.c. of turpentine was injected into the cellular tissue of the left thigh. Conditions improved at once and the temperature fell next day to 100° as the local inflammation developed. On Feb. 3rd the abscess was opened and many Gram-positive cocci were seen in the pus, from which also *Staphylococcus pyogenes albus* was recovered. The general condition rapidly improved, the patient could sleep, and "imperiously demanded food." By the 6th he had gained 10 lb. in weight, and all was going well when, on the 9th, he again relapsed. This time the fifth lumbar puncture showed a fluid clear and under slight pressure, with lymphocytes as the predominant cells. After this lumbar puncture he immediately improved, but suffered from slight post-febrile insanity for a time, ultimately being discharged cured, but still weak, after a little more than three months in hospital. Dr. Bourges considers the important points in the differential diagnosis of staphylococcal meningitis to be: the headache always frontal, the continuous pyrexia, the slower pulse, the more purulent cerebro-spinal fluid with blood in it and staphylococci. The fixation or artificial abscess is, he observes, useful in treating cases for which we have no antiserum. It acts first of all as a trap for microbes attracted into this new abscess, and probably also it stimulates additional formation of antibodies, thus increasing the bactericidal activity of the blood. It is, he thinks, of special advantage in staphylococcal or streptococcal infections.

### THE METROPOLITAN WATER-SUPPLY.

DURING the month of August, 1916, the rainfall (Thames basin) was 1'33 of an inch above the average mean rainfall for that month during the previous 33 years. The results of the chemical examination showed that all three raw Thames waters deteriorated or showed no change in quality, and the same was the case with the filtered waters. The quality compared favourably with the 1915 averages in both cases. Bacteriologically the raw Thames and New River waters contained fewer, and the raw Lee water more, bacteria than their respective averages, while the filtered waters yielded, generally speaking, not unsatisfactory results. In September the rainfall was 0'37 of an inch below the average mean rainfall for that month during the previous 33 years. Chemical examination showed that the raw Thames water improved slightly in quality according to the albuminoid test, but deteriorated as measured by the oxygen absorbed, turbidity, and colour tests. The filtered

waters showed a similar deterioration, including that shown by the albuminoid test. Both, however, showed results better than or equal to their respective averages in 1915. The raw Thames and Lee waters contained more, and the raw New River water fewer bacteria than their respective averages for the year 1915, while the filtered waters were satisfactory. In October the rainfall was 4·70 inches, or 1·48 inches above the average. Chemical examination in some respects showed a deterioration in regard to raw Thames and Lee waters, but an improvement in regard to raw New River water. There was also a certain deterioration shown in the filtered waters, but bacteriologically they were satisfactory, containing no typical *B. coli* even when 100 c.c. of the water were examined.

#### ANÆSTHESIA IN AMERICA.

THE publication of an American *Year Book of Anæsthesia and Analgesia* proves the interest which is expended in that country upon the study of anæsthetics, and affords also an index to the work done in the same direction. The editor, Dr. F. H. McMechan, explains that it had been intended to make the volume more international than it is, but we think that the loss of continental contributions is more than balanced by the gain of some peculiarly American features. Generally speaking, the most valuable and most striking portions of the book are those that deal, not so much with the practice of anæsthesia, as with its physiology and with the theories that endeavour to explain its causation and essential nature. Professor Ralph S. Lillie's thesis upon the physico-chemical theory of anæsthesia contains a well-reasoned discussion of current views, and puts forward excellent arguments for the belief that alterations in the physico-chemical properties of the plasma-membrane form the essential basis of anæsthesia. Whatever condition alters this structure so as to make it less capable of undergoing the changes of permeability and of electrical polarisation which normally accompany stimulation—and apparently other forms of cell activity—this condition has an inhibiting or paralysing effect on the cell. Professor Lillie's arguments supply an explanation of the action of all anæsthetic agents, and are therefore more inclusive than the views of Professor Benjamin Moore and Dr. H. E. Roaf which have hitherto received a large amount of attention and acquiescence. It is in the altered electrical conductivity of narcotised cells that Professor Lillie finds the most conclusive evidence of a decreased permeability during narcosis, pointing out that there appears to be a general relation between susceptibility to narcosis and the degree of organisation. Plants and lower organisms require higher concentrations of anæsthetic than higher animals; in vertebrates the cells most susceptible to narcosis are those of the higher brain centres. When organisation is destroyed many of the chemical processes of protoplasm, such as oxidations and fermentations, may continue and may be slowed by anæsthetics, but much higher concentrations of the latter are now necessary. This indicates that, when anæsthetics influence oxidative and other metabolic processes within the cell, they do so not directly, but through their influence upon some specially sensitive intermediary, which is a part of the organised structure

of the cell and itself controls the rate of the intra-cellular chemical processes. Thus Professor Lillie's arguments and facts appear to justify a conception of anaesthesia wider than that which was pictured by the statements of Professor Moore and Dr. Roaf. Other papers in the volume deal with blood changes under anaesthesia and with the origin of shock, with circulatory disturbances due to laparotomy, posture, and anaesthesia, and with blood pressure under anaesthesia. In addition there are articles describing work which is already well known, such as that of Dr. Wilfred Harris on injection of the Gasserian ganglion for trigeminal neuralgia and of Dr. Goodman Levy upon ventricular fibrillation. The editor contributes a profusely illustrated account of nasal administration of nitrous oxide; articles of a practical nature upon colonic ether-oil anaesthesia, upon delayed chloroform poisoning, and upon other and more unusual subjects, such as "The Use of Music during Anaesthesia," and "Some Psychic Factors of Anaesthesia," fill a volume which we hope will prove the first of a valuable series.

#### EXPERIMENTAL ATTEMPTS TO TRANSMIT PELLAGRA.

THE causation of pellagra is still enshrouded in doubt, investigators of the malady being at present divided mainly into two opposing parties, one attributing its origin to a specific infection, the other classing it as a dietary disease due to a deficiency of some essential substance or a want of balance in the staple articles of diet. The combat between these two opposing camps is more active in America than at home, the first hypothesis being supported by the Thompson-MacFadden Pellagra Commission of the New York Post-Graduate School, while the second finds a strenuous upholder in Dr. Joseph Goldberger, of the United States Public Health Service, who has for some time been specially investigating the malady. This expert has already published details (see THE LANCET of Jan. 8th, 1916) of the experimental production of pellagra by the continued use of a deficient or ill-assorted diet among some convicts in an American penitentiary who had volunteered to submit themselves for the test. In continuation of his observations he has undertaken a fresh series of experiments, the results of which have been recently published in the *United States Public Health Reports*. Assuming that if a specific infection existed it would probably be found either in the blood, the naso-pharyngeal secretions, the skin lesions, or in the excreta, Dr. Goldberger made attempts to transmit the malady by (1) the intramuscular or subcutaneous injection of blood, 5 to 7 c.c., from a sufferer into the system of healthy individuals; (2) the application of the pellagrins' naso-pharyngeal discharges by a swab to the healthy mucous membrane of the nose and naso-pharynx of the subjects of experiment; (3) the administration by the mouth of epidermic scales, up to 4 milligrammes, scraped from the pellagrous lesions of the skin; and (4) the ingestion of excreta—namely, urine up to 6 c.c., and faeces up to 8 grammes—from pellagrous cases by healthy persons. It may be explained that the scales, urine, and faeces were given in the form of pills, the material being mixed with bread or biscuit-crumbs and flour made into a pilular mass. The original number of persons who volunteered to submit to these extremely revolting experiments

was 20, of whom 13 were medical men, their ages ranging between 26 and 42 years, but it was found possible only to make use of 16 of them. The material for the tests was obtained from 17 pellagra patients of varying types and of different degrees of severity. The experiments were begun towards the end of last April and were continued to the end of June, so that a period of from four and a half to seven and a half months has elapsed since their initiation, long enough, it is thought, to enable a definite statement of the results to be made. Blood was furnished by 4 pellagrous persons, naso-pharyngeal discharges by 4, epidermal scales by 5, and urine and faeces by 16. Up to the date of report, early in November, not a single individual of those experimented upon developed any evidence to justify a diagnosis of pellagra, although, as might have been expected from the nature of the material swallowed, some four or five had immediate, but only temporary, gastro-intestinal disturbance. It would therefore appear that while the opinion that this disease is a communicable one gains no support from these experiments, the conclusion elsewhere drawn by Dr. Goldberger that it is an affection essentially of dietary origin brought about by a faulty, probably deficient, diet is materially strengthened.

#### UVEOPAROTID FEVER.

IN 1909 Heerfordt described by the name uveoparotid fever a new variety of infectious disease characterised by chronic inflammation of the parotid gland and of the uvea. His three patients each had bilateral parotid swelling and bilateral iridocyclitis, and two of them developed paralysis of a facial nerve in addition. The parotid swellings lasted for from 2 to 13 weeks, and so Heerfordt concluded that he was not dealing with cases of mumps; in addition, inquiry failed to show that his patients had been exposed to this infection, as no cases of epidemic parotitis in their neighbourhood could be heard of. He was able to find in the literature only two similar instances of this very chronic infection of the parotid glands and uveal tract, combined with facial paralysis. Dr. H. W. Leeksma, of Heukelum, has recently described<sup>1</sup> another instance of the disease. The patient, a married woman aged 28, felt tired early in January, and had cold shivers and night sweats, and in a few days' time had attacks of dizziness. On Jan. 21st she had pain in the left ear; on Feb. 2nd Dr. Leeksma found she had a right-sided Bell's palsy. On Feb. 8th the left parotid gland became swollen and painful. The Bell's palsy had cleared up by Feb. 21st, but two days later herpes of the left cornea occurred, and was followed by iridocyclitis. On March 3rd the right parotid gland swelled up, and on March 5th the right eye exhibited the signs of iridocyclitis. On April 10th a roseolous eruption appeared on the legs and remained for a fortnight. By April 25th the parotid swellings had vanished, and the iridocyclitis had improved in both eyes, though synchiae had appeared. On June 20th the affection of the left eye became suddenly worse, and the left parotid region was very painful. In August it was necessary to take the patient into an eye hospital for treatment. Dr. Leeksma found three typical cases of mumps occurring in the patient's environment in the month of February. He remarks that both iridocyclitis and facial paralysis are known to occur, though but

rarely, as complications of epidemic parotitis. He adds that the facial paralysis in the case he describes preceded the swelling of the parotid gland, and so cannot be attributed to the influence of mechanical pressure. He comes to the conclusion that Heerfordt's uveoparotid fever is nothing more or less than atypical mumps, and is not a new morbid entity. It should be added that the von Pirquet and Wassermann reactions in Dr. Leeksma's patient both proved negative.

#### THE TERCENTENARY OF BARTHOLIN.

Thomas Bartholinus, born Oct. 20th, 1616, died Dec. 4th, 1680, was one of Denmark's most famous men of science, and his tercentenary is celebrated by the October issue of *Janus*, which is given over to a record of his life and works. He was born in Copenhagen, the son of a well-known University professor. After a course of study at the Copenhagen University he went abroad to study at the age of 21. It is interesting to note that this period of travel and learning occupied ten years. All the while, it is said, he studied and wrote with the greatest diligence. He returned to Copenhagen and was appointed to the chair of anatomy. At the early age of 44 he moved to his estate and lived afterwards in peaceful retirement, so that he made all his important discoveries during the short space of 14 years. Bartholin's claim to fame rests upon his discovery of the thoracic duct and the lymphatic system in man. A man, tranquil in temperament and capable of enjoying to the full the social glamour and fame he rapidly gained, it is said that he often wished he had never found the small, scarcely visible lymphatic vessels, because of all the strife, controversy, and annoyances associated with their discovery. Bartholinus lived in ample and generous days, when distinction in one sphere of life did not preclude honour in other walks, for besides occupying various public offices he was also a judge of the Supreme Court. It was his son, Caspar Bartholinus, who discovered the glands, called after his name, in the vagina, and the ductus Bartholinianus. He, like his father, appears to have early given up scientific work. He entered the Civil Service and gained a patent of nobility which was conferred not only upon him but reverted back to his father, who had been dead for 50 years.

#### THE LANCET, VOL. II., 1916 : THE INDEX.

THE Index and Title-page to the volume of THE LANCET completed with the issue of Dec. 30th will be ready early in the New Year. Owing to the continued shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a post-card to the Manager, THE LANCET Office, 423, Strand, London, W.C., when a copy of the Index and Title-page will be supplied free of charge.

Dr. E. Coey Bigger has been appointed a Commissioner of the Irish Local Government Board in the room of Sir Thomas Stafford, who has resigned. Dr. Bigger is one of the inspectors of the Board, and was a member of the Vice-Regal Committee on the Poor Law whose far-reaching report attracted great attention some ten years ago.

<sup>1</sup> Nederl. Tijdschr. v. Geneeskunde, Amsterdam, 1916, II., 1126.

## DENTIFRICES.

**M**ODERN dentifrices may be divided broadly into four groups: (1) Powders, (2) pastes, (3) solid soaps, and (4) fluids. The demand of the public appears to be in favour of powders, pastes, and soaps, the presence of a mechanical agent in these being appreciated while such is usually omitted from fluid preparations. Of 19 samples of dentifrices which we recently purchased in the open market seven were powders, eight were pastes, two were solid soaps, and two were clear fluids. Many formulas of dentifrices have been published from time to time, and in most cases the design appears to aim at securing the combined offices of a germicide, antifermenative, deodorant, antacid, and a mechanical detergent. Such a combination presents no difficulty in the making, but it is important that the materials chosen should be carefully prepared and blended and free from injurious constituents, and that the whole result should be attractive. It is the invasion of the enamel by disease organisms which begins in many cases the degradation of the tooth, and the process of decay, unless arrested, leads eventually to that exquisite trouble so widely experienced. This has led to the policy of maintaining mouth asepsis, the careful cleansing of the teeth being now put into very general practice by the daily use of the tooth-brush and a dentifrice. A dentifrice may clearly do more harm than good if it is carelessly prepared or contains inappropriate constituents, and its choice is therefore important.

According to THE LANCET Laboratory examination a constituent common in dentifrices is chalk, and as an antacid it has claims, but it possesses no germicidal or antifermenative properties, and though serving as an effective mechanical detergent may, unless it is a finely triturated preparation, injure the enamel by erosive action. It should, in other words, be free from gritty particles which are likely to scratch. Other mechanical detergents are employed, as, for example, silicious substances like kieselguhr and talc, which, however, have no acid-neutralising properties and may contain particles capable of producing injury to the enamel. A finely comminuted mechanical detergent containing an effective antiseptic seems desirable, but it is extremely important that this detergent should be perfectly smooth and free from gritty particles. The removal from the cavities of the teeth of decaying particles of food which are readily

hydrolysed and fermentable is not always possible by the toothbrush alone, and it has been said on good authority that the chewing of coconut or even an apple acts as an effective scourer of the teeth with the free use of the wet brush afterwards.

Soap, again, is a very common constituent of dentifrices and is often associated with chalk. It serves, of course, as a cleanser and antacid and there can be little objection to its use. It also acts as an adjuvant favouring the formation of a uniform emulsion. Amongst other adjuvants or excipients used in dentifrices are glycerine and sometimes sugar.

Amongst the antiseptics chosen is a wide range of essential oils and aromatics, all of which possess more or less germicidal properties. Popular amongst these are thymol, carbolic acid, hydrogen peroxide, benzoic acid, wintergreen, and the mint oils. Cinnamon also is a favourite, and it is known to have valuable antiseptic properties.

These generalities considered, we may pass to the actual results of our examination of a number of dentifrices which fairly represent the kind in public use at the present time. We deal with them in the order already set out, which is as follows: (1) Dry powders; (2) pastes; (3) solid soaps; and (4) fluids.

(1) *Dry powders*.—As will be seen from the accompanying table, these all contained chalk (mostly represented in an insoluble ash effervescing in acids) in prominent quantity, the percentage amount lying between 32·33 and 88·12. In many cases the chalk was not finely comminuted, as an inspection of the table will show. With two exceptions soap was present and an antiseptic, such as phenol and thymol, and essential oils, of which eucalyptus appeared to be in favour. One contained a decided amount of sugar and in others starch granules, the desirability of which is doubtful. In two instances the powders were found to yield available oxygen on suitable treatment. These preparations would probably have a slight bleaching effect on the teeth. Most of the powders were agreeably perfumed, and in certain cases orris root was a considerable constituent.

(2) *Pastes*.—The pastes showed, generally speaking, a wider range of composition than the other preparations examined. The substances found included chalk, sugar, soap, starch granules, silica, areca, and germicidal substances, amongst which were benzoic acid, wintergreen, thymol, mint, and other essential oils. In one case in which

## THE COMPOSITION OF DENTIFRICES.

Number of dentifrice.	Moisture.	Ash.	Insoluble ash (chiefly chalk).	Soluble alkali as Na <sub>2</sub> O.	Alcoholic extract (chiefly soap and glycerine).	Microscopical observations.	Antiseptic agents.	
POWDERS.	1	0·54	88·82	88·12	0·68	0·46	Uniformly sized chalk particles, with a few angular pieces ; starch present.	Aromatics.
	2	8·27	63·28	62·66	0·64	3·20	Uniformly sized chalk particles, but not well levigated ; starch present.	Phenols.
	3	7·15	38·00	32·33	3·25	2·40	Starch granules, fine chalk particles, but not uniformly distributed.	Aromatics.
	4	1·50	82·00	77·50	3·96	3·00	Well-levigated, uniformly sized chalk particles, quite non-gritty.	Essential oils, peppermint.
	5	Nil.	71·20	66·43	4·23	10·40	Well-communited chalk, with starch granules, non-gritty.	Wintergreen.
	6	3·50	59·50	47·91	1·40	4·40	Fine, smooth chalk particles, non-gritty.	Clove, essential oils, available oxygen.
	7	3·20	64·90	60·99	3·38	16·04	A finely comminuted powder, free from irregular particles.	Oxygen and thymol.
PASTES.	8	2·00	11·80	11·20 (silica)	0·53	36·84	Irregular sized mineral particles, with starch granules.	Aromatics.
	9	32·75	33·00	29·13	3·44	34·20	Smooth and well-communited chalk quite free from gritty particles.	Peppermint, thymol.
	10	26·31	21·44	14·74	5·91	42·64	Particles irregular in size, comminution not good.	Thymol, wintergreen.
	11	14·62	13·21	11·16	1·37	51·44	Starch granules and a few irregular mineral particles.	Aromatics.
	12	26·62	21·12	16·98	3·67	53·36	Contained a well-communited powder, perfectly smooth and free from grit or irregularities.	Benzoic and essential oils, peppermint, &c.
	13	18·58	32·43	20·20	10·80	35·44	Irregular particles ; the chalk not sufficiently comminuted ; some starch.	Essential oils.
	14	23·10	36·58	36·04	0·47	32·00	Very fine and smooth chalk particles well comminuted.	Menthol.
SOAP.	15	20·35	19·32	18·61	0·60	51·64	Somewhat coarse particles, showing defective levigation ; some starch.	Thymol, eucalyptus.
	16	5·60	35·70	22·98	11·20	71·42	Good round particles of chalk, but capable of further levigation.	Aromatics, essential oils.
	17	4·89	28·44	13·86	12·20	81·25	Good smooth and regularly sized chalk powder present.	Essential oils, perfume.
FLUIDS.	18	99·83 (alcoholic)	Nil.	—	—	—	Clear fluid.	Essential oils, menthol.
	19	72·02 (alcoholic)	1·63	Nil.	1·40	27·98	Clear fluid.	Aromatic and essential oils.

thymol was used the preparation had a rather sharp, stinging effect on the tongue. On the whole the chalk present in these pastes was in a much better state of comminution than in the dry powders. In this respect some were decidedly superior to others. As the microscope showed, the mechanical detergent was here and there crude, presenting irregularly sized and gritty particles likely to damage in the long run the enamel of the teeth. It is most desirable that chalk and kindred mechanical agents should be very finely triturated. Where this was the case the dentifrices were excellent in their effect and very agreeable to use. The presence of sugar, both cane and glucose, may be open to objection, and it is probable that these substances have recently replaced glycerine owing to the restrictions on the supply caused by the extensive use of this substance for war purposes. Another hydrolysable carbohydrate, starch, does not appear to be a desirable ingredient of a dentifrice.

(3) *Soap dentifrices.*—Soap tablets for purposes of cleansing the teeth are commonly combined with some chalk or phenol or essential oils. The oils are generally of the character of perfumes, and cinnamon seems useful. On the whole, the chalk in these preparations was fairly well comminuted, but some specimens might well be improved in this respect.

(4) *Fluid dentifrices.*—These consisted generally of a solution of essential oils in spirit. When added to water a milky fluid results, which, however, can possess little if any mechanical detergent action to speak of. In one case there was also dissolved in the spirit some soap.

In conclusion, we do not pretend to have exhausted the subject, but we think that sufficient information has been obtained in the course of the inquiry to show the chief points in regard to the composition and character of the dentifrices which find public patronage.

## THE CONTROL OF VENEREAL DISEASES.

### *Scheme for the City of London.*

THE City Corporation has recently approved a scheme for the treatment of venereal diseases, and the work will be carried out in conjunction with the authorities of St. Bartholomew's Hospital. A special centre will be established in a building erected several years ago by the Corporation for use as a hospital. Here will be held a clinic at which will be treated cases in the communicable stage, and, in addition, at least ten beds will be available for in-patient treatment. Other beds, as may be found necessary, will be provided in the hospital. Adequate provision for teaching and demonstration purposes has been arranged. The hospital authorities will be responsible for the administration and staffing of the centre. In addition to the necessary nursing and general assistance, the work will be in charge of a member of the hospital staff, assisted by a senior whole-time medical officer. A new junior appointment will be created at the hospital, and this medical officer will divide his time between the work in the skin department and the new department. The entire resources of the hospital, as in the case of the tuberculosis dispensary, will be available for assistance in special cases. The simpler bacteriological work will be done at the centre, but all investigations requiring special tests or cultural methods will be under the charge of the pathologist of the hospital and will be carried out in his laboratory. The usual provision of outfits for the forwarding of pathological specimens by medical practitioners, the free distribution of salvarsan, and arrangements for necessary consultations have been provided for. Dr. W. J. Howarth, medical officer of health of the City of London, will arrange to deliver lectures to the staffs of city firms and will be assisted by a woman doctor, who will lecture to women. It is proposed that St. Bartholomew's Hospital shall receive a sum of £1800 for the first year's work (not to include the cost of salvarsan). The necessary equipment and alterations will involve a capital expenditure, in addition, of about £1000.

At the same time as the scheme came up for consideration the Court of Common Council approved resolutions recording their opinion:—

(a) That administrative measures for the diagnosis and treatment of venereal diseases will only attain their maximum effectiveness in protecting the public health when the treatment of such diseases by unqualified persons is prevented by law.

(b) That it is desirable that the recommendation 58 (III.) of the Patent Medicines Committee of the House of Commons endorsed by the Royal Commission on Venereal Diseases, "That all advertisements of remedies for diseases arising from sexual intercourse or referring to sexual weakness be prohibited," should at once be carried out.

The following resolution was also passed by the Sanitary Committee:—

That it be referred to the medical officer of health to report, at the termination of six months, on the working of the scheme for the treatment of venereal diseases in the City, and to submit such information as may have been collected bearing on the desirability of compulsory notification and compulsory treatment of these diseases; and further to consider and report whether special legislative action is necessary to prevent persons suffering from venereal disease from engaging in occupations associated with the food-supply.

### *Early Experience of Statistical Notification in Western Australia.*

Dr. R. C. Everitt Atkinson, Commissioner of Public Health for Western Australia, sends us a report on the working of the first months of a scheme of confidential statistical notification of venereal diseases.<sup>1</sup> Forms of notification were sent to medical men early in June, and 70 have responded. Of the total of 563 cases reported up to Sept. 30th as "not previously under treatment for the present infection," 181 were of syphilis, an unusually high proportion probably explained by the much longer treatment required for syphilis than for gonorrhoea. In October the numbers of fresh notifications were: syphilis 33, gonorrhoea 91, chancroid 9. The Commissioner comments upon the flagrant disproportion between the numbers notified for the two sexes; whereas 155 cases of syphilis and 333 of gonorrhoea were notified in males, there were only 26 and 29 cases respectively notified in females. He concludes that females are much less inclined to seek medical advice, and states that the problem of dealing with the many cases of gonorrhoea in females not under medical treatment is receiving careful attention.

### *Routine Treatment of Venereal Diseases.*

At the request of the National Council for Combating Venereal Diseases a sketch of the routine treatment for venereal diseases as carried out at the military hospital in Rochester-row has been drawn up by Lieutenant-Colonel L. W. Harrison, the officer in charge. In the preface to this pamphlet of 14 pages Colonel Harrison states that there is no finality in the treatment of venereal diseases, and the outline is to be regarded simply as a bulletin of progress. Thus regarded, its appearance is timely, and the outline will serve a most useful purpose. The methods of treatment given are those which have stood the test of practice in the critical atmosphere of a teaching centre. The pamphlet is published by the National Council at Bank Buildings, Kingsway, London, W.C., price 2d. (post free 2½d.).

### *Treatment of Pregnant Women.*

The hospital accommodation for pregnant women is occupying the attention of the National Council for Combating Venereal Diseases. In consequence of the reluctance of the principal lying-in hospitals in London to receive such cases, many innocent sufferers have heretofore been compelled to enter Poor-law infirmaries if in need of institutional treatment. A recent conference between the National Council and the medical boards of these hospitals is likely to result in remedying this situation.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

### *Canadian Research Board.*

THE Federal Government has announced the creation of a National Scientific and Industrial Committee for Canada, and has indicated the programme to be carried out by the new body. For the direction of this work the whole time and service have been requisitioned of Professor A. B. MacCallum, F.R.S., professor of biochemistry in the University of Toronto, and President of the Royal Society of Canada. As chairman of a National Scientific and Industrial Committee, Professor MacCallum will bring to the discharge of his duties ripe experience and educational qualifications of the highest academical value. The first duty of the committee will be to outline plans and mature measures for scientific research which will later prove of benefit to the industrial interests of

the Dominion. Amongst some of the plans anticipated will be a scientific study of Canada's unused resources, the waste and by-products of farms, forest, fisheries, and industries. Trained and competent research men will be added to the staff as the work progresses, and the public are to be kept duly apprised of the results of the investigations.

#### *Pension and Discharge Boards.*

Mr. J. K. L. Ross, Montreal, has been appointed by the Federal Government chairman of the Canadian Permanent Pension Board. The medical member is Major J. L. Todd, associate professor of parasitology in McGill University. Major Todd made a careful study of pensions in England and France, and for a time served on the Pensions and Claims Board of England. Pensions will be awarded in direct proportion to the disability incurred, and disabled men discharged from the Canadian Army will be divided into six classes :—I., Total disability, 100 per cent.; II., Disability, 80 per cent.; III., Disability, 60 per cent.; IV., Disability, 40 per cent.; V., Disability, 20 per cent.; VI., Disability under 20 per cent. In the several military districts sub-boards are being appointed. The Military Hospitals Commission of Canada is appointing Discharge Boards to examine convalescent soldiers who are eligible for pensions. In Manitoba, Dr. H. H. Chown, Dr. Popham, and Dr. Galloway have been appointed, all of Winnipeg. In British Columbia, Dr. O. M. Jones and Dr. R. L. Fraser, Victoria, and Dr. W. J. C. Towlin. Lieutenant-Colonel Mackenzie Forbes has been appointed medical officer of the Hospitals Commission in Montreal.

#### *The Tuberculous Soldier in Canada.*

The Military Hospitals Commission of Canada is considering the problem of the tuberculous soldier when he arrives home from abroad, as well as the man who has enlisted for overseas service, but who was found to be tuberculous before being sent across the Atlantic. A committee of experts have advised the temporary treatment of these soldiers in existing sanatoria and the purchase of properties in localities suitable for the treatment of tuberculous cases. The western provinces have been provided for by the securing of the sanatorium at Frank, Alberta, which contains 120 beds. With the existing sanatoria at Tranquille (B.C.), Ninette (Manitoba), and Calgary, sufficient accommodation is available for Western Canada at present. The lower provinces will find accommodation partly in Quebec, St. John (N.B.), Kentville (N.S.), and Charlottetown (P.E.I.). In Ontario the Sir Oliver Mowat Institution at Kingston, and the Hamilton and London buildings have been secured. The two latter are to be materially enlarged by the joint aid of the Hospitals Commission, the Ontario Government, and the municipalities of Hamilton and London respectively.

#### *The Clayton Convalescent Home, Halifax, N.S.*

A convalescent home—the first of its kind—was recently opened in Halifax (N.S.) for the education, vocational, and physical training of disabled soldiers. Although such training is now in progress in other institutions of Canada, this is the first devoted exclusively to the work. The founder, Mr. W. J. Clayton, Halifax, has presented it to the Hospitals Commission. Provision has been made for instruction in cobbling, tailoring, and automobile driving. Arrangements are in progress for other trades. The first soldiers to be admitted were 17 from Jamaica who suffered from frost-bite last winter while on a transport going to England, necessitating the amputation of one or both feet.

#### *Infantile Paralysis in Ontario.*

The Ontario Board of Health are meeting with success in the prompt steps taken for combating infantile paralysis. In September there were 76 cases in the province with 7 deaths, while in October there were 31 cases with 7 deaths. The cases in October were scattered over 17 counties without concentration in any particular locality.

#### *The Problem of the Feeble-minded in Toronto.*

A recent session of the Public Health Section of the Academy of Medicine, Toronto, was devoted to a symposium on the subject of the feeble-minded in Toronto, which was opened by Dr. Clair M. Hincks, the present head in succession to the founder, Dr. Charles K. Clarke, of the Psychiatric Clinic, at the Toronto General Hospital. Dr. Hincks related the results of an investigation lasting over two and a half years and dealing with 1445 examinations. 50 per cent. of the feeble-minded cases

examined were known to be criminals and 285 of them habitual thieves, all of whom were still at large in the city. Fifty-nine people examined expressed a delight in burning down buildings and 120 admitted to murderous intentions; these also were still roaming the streets. 60 per cent. of all the social victims on the streets were stated to be feeble-minded. There were also examined 201 feeble-minded school-children regarded as absolutely incorrigible, 53 being sexually abnormal; they were still mixing with the normal children of the schools. These facts, the speaker said, were of the most pressing interest to the municipal and provincial educational authorities. Dr. Clarke agreed with the speaker that the problem of the feeble-minded must be forced upon the attention of the authorities, and no longer be allowed to fall between the provincial and the municipal bodies. The meeting passed a resolution in favour of increased institutional care for the mentally defective at the earliest possible date.

Dec. 13th, 1916.

#### PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *Infant Welfare in Paris during the Second Year of War.*

Professor Pinard recently made a communication to the Academy of Medicine on the protection of infant life in Paris during the second year of war. With protective measures similar to those of the preceding year, the figures of the second year are nevertheless not so good. At 95 per cent. of the 26,179 registered births the Assistance Publique rendered aid. The percentage of stillbirths rose from 6.6 to 7.7; the proportion of infants put out to nurse from 13 to 22 per cent.; the maternal mortality from 0.46 to 0.48 per cent. The greater number of abandoned infants (5.2 instead of 2.9 per cent.) and of premature births, and the diminution of the average weight at birth, all these are attributed to economic causes which M. Pinard vigorously denounces—namely, the presence in munition works of pregnant and nursing women. He demands the exclusion from the factory of both these classes, as well as the woman who has been delivered less than six months. To this drastic remedy M. Strauss took exception in view of the stern necessity of the war, and upon his suggestion discussion on M. Pinard's communication was postponed until a later meeting.

#### *The Excellent Sanitary State of Paris.*

M. Deslandres, a municipal councillor, has drawn up for his colleagues an important report on the working of the vaccination service from the beginning of hostilities. He states that during 28 months of warfare there have been registered in Paris a grand total of 3 cases of variola, 3 cases of varioloid, with a single death. The last case was noted on Dec. 15th, 1915, and the year 1916 has been unique in the statistics in having to its credit no single case of either variola or varioloid. These results are the outcome of the zeal of M. Guilhand who directs the vaccination service. For the first time in history a war on French territory has been unaccompanied by an outbreak of small-pox.

#### *Treatment of Gunshot Wounds with Ointments.*

M. Paul Gibbon recommends a reversion to the old treatment of wounds by the employment of ointment, confining its use to the long suppurative tracks produced by shell explosion. After opening up the wound he applies an ointment consisting of : aristol and dermatol in 1:5, salol 6, lanolin 30, and vaseline 30 parts. The dressing is changed every 2-4 days. He reports the relief of pain as almost immediate and a surprising rapidity in the process of healing.

#### *Antisyphilitic Measures in Morocco.*

These have recently been the subject of an important communication by Dr. Leredde to the Paris Society of Medicine. Syphilis is universal among the native population of Morocco and spreads widely from it to the army and the European population. The measures taken by the Service de Santé have aimed at sterilisation, particularly in the soldier, during the initial period by means of modern methods and eliminating by early preventive treatment the later manifestations of the disease. Soldiers with a chancre of whatever nature are directed to the subdivisional ambulance,

and, if the spirochete is demonstrated by microscopical examination, energetic treatment at once follows. Treatment centres and laboratories have been set up in the principal towns in Morocco for dealing with civilian disease. Lastly, measures have been taken to divide the prostitute into three classes: non-syphilitic, infectious syphilitic, and non-infectious tertiary. In the second class energetic antisyphilitic treatment is applied. These measures, initiated by General Lyantey and ably organised by Dr. Leredde, are the first serious attempt to deal with the evil in Morocco, and good results are to be looked for.

#### *The Action of Picric Acid on Blue Pus.*

Blue pus has been frequent in the course of healing wounds at base hospitals, especially where fistulae have been present leading down to bone—e.g., resections, osteomyelitis, purulent pleurisy. The antiseptics usually employed—alcohol, iodine, formalin—are toxic, tend to produce or keep up a dermatitis, and kill the newly formed tissue cells. At an Army Medical reunion at the Beauvais centre, Dr. Chazairain showed that 1 per cent. picric acid solution causes a rapid disappearance of blue pus without fear of general or hepatic toxic action and stimulates at the same time the active replacement of epidermic cells.

Jan. 1st.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census 6599 births and 7863 deaths were registered during the week ended Saturday, Dec. 23rd, 1916. The annual rate of mortality, which had steadily increased from 13·0 to 20·3 per 1000 in the five preceding weeks, further rose in the week under notice to 23·7 per 1000 of their aggregate civil population estimated at 17,312,255 persons for the year 1915. During the first 12 weeks of the quarter just ended the mean annual death-rate in these towns averaged 15·1, against a corresponding rate of 15·6 per 1000 in London. Among the several towns the death-rate during the week ranged from 9·4 in Lincoln, 12·4 in Barnsley, 13·5 in Ilford, 14·3 in Rhondda, and 14·4 in Smethwick, to 35·0 in Oxford, 34·8 in Southport, 35·1 in Hastings, and 39·7 in Bournemouth.

The 7863 deaths from all causes were 1138 in excess of the number in the previous week, and included 236 which were referred to the principal epidemic diseases, against 226 and 230 in the two preceding weeks. Of these 236 deaths, 83 resulted from measles, 63 from infantile diarrhoeal diseases, 53 from diphtheria, 19 from whooping-cough, 10 from scarlet fever, and 8 from enteric fever, but not one from small-pox. The annual death-rate from these diseases was equal to 0·7 per 1000, and corresponded to that recorded in each of the three preceding weeks. The deaths attributed to measles, which had been 47, 56, and 50 in the three preceding weeks, rose to 83, and included 31 in London, 8 in Coventry, 7 in Manchester, 6 each in Birmingham and Liverpool, 5 in Edmonton, and 3 in Warrington. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had declined from 477 to 82 in the 14 preceding weeks, further fell to 63, of which 14 were registered in London, 7 in Manchester, 6 in Birmingham, and 3 each in Stoke-on-Trent, Liverpool, Leeds, and Rhondda. The fatal cases of diphtheria, which had been 50, 47, and 61 in the three preceding weeks, fell to 53, and included 11 in London, 5 in Stoke-on-Trent, and 4 each in Birmingham and Manchester. The deaths attributed to whooping-cough, which had been 16, 23, and 18 in the three preceding weeks, numbered 19, of which 4 occurred in London and 3 in Bristol. The deaths referred to scarlet fever, which had increased from 6 to 12 in the four preceding weeks, fell to 10, and included 2 each in London and Manchester. The 8 cases of enteric fever were slightly below the average in the earlier weeks of the quarter, and included 2 each in London and Nottingham.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had declined from 1171 to 1012 in the six preceding weeks, further fell to 922 on Saturday, Dec. 23rd; 100 new cases were admitted during the week, against 120, 103, and 100 in the three preceding weeks. The cases of diphtheria numbered 1445, against numbers declining from 1584 to 1473 in the four preceding weeks; 136 new cases were admitted during the week, against 171, 169, and 158 in the three preceding weeks. The 223 deaths from all causes in London were 222 in excess of the number recorded in the previous week, and corresponded to an annual death-rate of 24·5 per 1000. The deaths referred to diseases of the respiratory system, which had steadily increased from 132 to 524 in the nine preceding weeks, further rose to 650 in the week under notice. The deaths from influenza numbered 86, against 55 and 81 in the two preceding weeks.

Of the 7863 deaths from all causes in the 95 towns, 253 resulted from violence, 557 were the subject of coroners' inquests, and 2070 occurred in public institutions. The causes of 106, or 1·3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Salford, and in 60 other smaller towns. Of the 106 uncertified causes, 20 were registered in Birmingham, 19 in Liverpool, 8 in Manchester, 5 each in South Shields and Gateshead, and 4 each in London, Barrow-in-Furness, and Stockton-on-Tees.

In the 96 English and Welsh towns 5629 births and 7260 deaths were registered during the week ended Saturday, Dec. 30th, 1916. The annual rate of mortality, which had increased from 13·0 to 23·7 per 1000 in the six preceding weeks, fell to 21·9 per 1000 in the week under notice. During the 13 weeks of last quarter, the mean annual death-rate in these towns averaged 15·6, against 16·1 per 1000 in London.

During the week the death-rate ranged from 10·8 in Grimsby, 11·4 in Barnsley, 11·5 in Smethwick, 12·2 in Abberdare, and 15·5 in Ilford, to 29·6 in Reading, 31·0 in Norwich, 31·6 in Rotherham, 33·7 in Bath, and 35·3 in Warrington.

The 7260 deaths from all causes were 603 below the number in the previous week, and included 229 which were referred to the principal epidemic diseases, against 230 and 236 in the two preceding weeks. Of these 229 deaths, 80 resulted from infantile diarrhoeal diseases, 66 from measles, 42 from diphtheria, 26 from whooping-cough, 8 from scarlet fever, and 7 from enteric fever. The annual death-rate from these diseases was equal to 0·7 per 1000, and coincided with that recorded in each of the four preceding weeks. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had steadily declined from 477 to 63 in the 15 preceding weeks, rose to 80, and included 30 in London, 5 in Birmingham, 4 in Liverpool, and 3 each in Leicester and Manchester. The deaths attributed to measles, which had been 56, 50, and 83 in the three preceding weeks, fell to 66, of which 25 occurred in London, 8 in Coventry, 6 in Edmonton, and 4 each in Manchester and Sheffield. The fatal cases of diphtheria, which had been 47, 61, and 53 in the three preceding weeks, further fell to 42, and included 7 in London and 3 each in West Ham and Birmingham. The deaths attributed to whooping-cough, which had been 23, 18, and 19 in the three preceding weeks, rose to 26, but showed no great excess in any town. The deaths referred to scarlet fever, which had been 8, 12, and 10 in the three preceding weeks, fell to 8, and included 2 each in Liverpool and Salford. The 7 fatal cases of enteric fever, of which 2 were registered in Bury, were 2 below the average in the earlier weeks of the quarter.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had declined from 1171 to 922 in the seven preceding weeks, rose to 934 on Saturday, Dec. 30th; 86 new cases were admitted during the week, against 103, 100, and 100 in the three preceding weeks. The cases of diphtheria numbered 1485, against numbers declining from 1582 to 1445 in the five preceding weeks; the admissions during the week were 113, against 169, 158, and 136 in the three preceding weeks. These hospitals also contained on Saturday last 257 cases of measles, 48 of whooping-cough, and 37 of enteric fever. The 1932 deaths from all causes in London were 66 below the number in the previous week, and corresponded to an annual death-rate of 23·7 per 1000. The deaths referred to diseases of the respiratory system, which had steadily increased from 132 to 650 in the ten preceding weeks, fell to 645 in the week under notice. The deaths from influenza numbered 98, against 81 and 86 in the two preceding weeks.

Of the 7260 deaths from all causes in the 96 towns, 241 resulted from violence, 597 were the subject of coroners' inquests, and 1943 occurred in public institutions. The causes of 97, or 1·3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Hull, and in 61 other smaller towns. Of the 97 uncertified causes 19 were registered in Birmingham, 18 in Liverpool, 6 in Gateshead, 5 each in Warrington and Sheffield, and 4 each in Manchester and Barrow-in-Furness.

### HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,372,000 persons at the middle of this year, 1015 births and 794 deaths were registered during the week ended Saturday, Dec. 16th, 1916. The annual rate of mortality, which had been 15·4, 15·8, and 16·4 per 1000 in the three preceding weeks, rose to 17·5 per 1000 in the week under notice. During the first 11 weeks of the quarter just ended the mean annual death-rate in these towns averaged 14·5, against a corresponding rate of 14·3 per 1000 in the large English towns. Among the several towns the death-rate during the week ranged from 10·7 in Hamilton, 12·7 in Kirkcaldy, and 14·0 in Ayr, to 20·5 in Dundee, 23·0 in Perth, and 24·8 in Leith.

The 794 deaths from all causes were 47 in excess of the number in the previous week and included 37 which were referred to the principal epidemic diseases, against numbers declining from 53 to 38 in the three preceding weeks. Of these 37 deaths, 11 resulted from measles, 10 from infantile diarrhoeal diseases, 7 from whooping-cough, 5 from scarlet fever, 3 from diphtheria, and 1 from enteric fever, but not one small-pox. The annual death-rate from these diseases was equal to 0·8, against 0·7 per 1000 in the large English towns. The deaths attributed to measles, which had been 20, 16, and 12 in the three preceding weeks, numbered 11, of which 6 occurred in Dundee and 3 in Glasgow. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had been 18, 10, and 14 in the three preceding weeks, fell to 10, and included 4 in Glasgow. The fatal cases of whooping-cough, which had been 1, 6, and 3 in the three preceding weeks, rose to 7, and comprised 2 each in Glasgow, Edinburgh, and Dundee, and 1 in Leith. The 5 deaths attributed to scarlet fever were slightly in excess of the average in the earlier weeks of the quarter, and included 2 each in Aberdeen and Clydebank. The deaths referred to diphtheria, which had been 9, 9, and 6 in the three preceding weeks, fell to 3, which were recorded in Glasgow, Aberdeen, and Kilmarnock respectively. The fatal case of enteric fever and one typhus were registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 131, 118, and 155 in the three preceding weeks, rose to 191 in the week under notice, but were 17 below the number registered in the corresponding week of 1915. The deaths from violence numbered 34, against 26 in each of the two preceding weeks.

In the 16 Scotch towns 959 births and 892 deaths were registered during the week ended Saturday, Dec. 23rd. The annual rate of mortality, which had increased from 13·8 to 17·5 per 1000 in the three preceding weeks, further rose to 19·6 per 1000 in the week under notice. During the first 12 weeks of the quarter just ended the mean annual death-rate in these towns averaged 15·0, against 15·1 per 1000 in the large English towns. Among the several towns the death-rate during the week ranged from 10·7 in Falkirk, 12·4 in Motherwell, and 12·6 in Clydebank, to 24·0 in Coatbridge, 24·1 in Paisley, and 30·1 in Perth.

The 892 deaths from all causes were 98 above the number in the previous week, and included 46 which were referred to the principal epidemic diseases. These 46 deaths corresponded to an annual rate of 1·0 per 1000, and included 14 from measles, 12 from whooping-cough, 9 from infantile diarrhoeal diseases, 6 from diphtheria, 4 from scarlet fever, and 1 from enteric fever. The deaths attributed to measles,

which had declined from 20 to 11 in the four preceding weeks, rose to 14, and comprised 9 in Dundee, 2 each in Glasgow and Edinburgh, and 1 in Leith. The deaths referred to whooping-cough, which had been 6, 3, and 7 in the three preceding weeks, rose to 12, of which 5 occurred in Glasgow. The fatal cases of infantile diarrhoea, which had been 10, 14, and 10 in the three preceding weeks numbered 9, and included 3 in Glasgow and 2 in Edinburgh. The deaths from diphtheria were slightly below the average in the earlier weeks of the quarter, and showed no excess in any town. Two of the 4 deaths attributed to scarlet fever and the fatal case of enteric fever were recorded in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 118, 155, and 191 in the three preceding weeks, further rose to 227 in the week under notice, and were 72 in excess of the number registered in the corresponding week of 1915. The deaths from violence numbered 33, against 26 and 34 in the two preceding weeks.

#### HEALTH OF IRISH TOWNS.

In the registration area of Dublin 99 births and 195 deaths were registered during the week ended Saturday, Dec. 23rd, 1916. The deaths were equal to an annual rate of 25·6, against 24·5 and 19·6 per 1000 in London and Glasgow respectively, and included 25 of infants under 1 year and 69 of persons aged 65 years and upwards.

Nine deaths were referred to infantile diarrhoea, 2 to measles, and 1 to enteric fever. The causes of 5 deaths were uncertified and those of 2 others were the subject of coroners' inquests, while 76 of the total deaths occurred in public institutions.

During the same period 146 births and 173 deaths were registered in the city of Belfast. The death-rate was equal to 23·1, or 4·1 per 1000 above that in the previous week. The total deaths included 18 of infants under 1 year and 46 of persons aged 65 years and upwards. Three deaths were referred to measles, 2 to enteric fever, and 1 to scarlet fever. The causes of 3 deaths were uncertified and those of three others were the subject of coroners' inquests, while 51 of the total deaths occurred in public institutions.

#### THE SERVICES.

##### ROYAL NAVAL MEDICAL SERVICE.

The following appointments have been notified:—Fleet-Surgeons: J. R. Muir to Wet-Hai-Wel Sick Quarters; J. S. Dudding to *Tiger*; and R. B. Scribner to *Pembroke*. Temporary Surgeons: W. H. Butcher to *Victory*; and M. O. Hunter to *Hastor* Hospital.

##### ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. H. E. Winter is retained on the Active List, and to be supernumerary.

To be Lieutenant-Colonels: Major L. C. Parkes, R.A.M.C. (T.F.), Major A. Carless, R.A.M.C. (T.F.), and Major G. R. Phillip, C.A.M.C.

Temp. Major G. B. Price to be temporary Lieutenant-Colonel.

To be temporary Majors: Temp. Lieut. J. L. Birley (whilst employed on special duty), Capt. G. P. Taylor, and Temp. Capt. W. Penberthy (whilst commanding troops on a hospital ship).

To be temporary Captains: O. D. Rilance, C.A.M.C., C. P. Bligh-Wall, S.Afr.M.C., K. Bremer, S.Afr.M.C., S. Copley, S.Afr.M.C., J. C. Caldwell, S.Afr.M.C., Temp. Lieut. A. W. G. Murray, and Temp. Lieut. P. R. Lowe.

Temporary Captains relinquishing their commissions: J. D. Nicolas, W. J. G. Gayton, and S. Greenwood (on account of ill-health).

Temporary Lieutenants relinquishing their commissions: R. W. Halliday, H. C. Sutton, T. B. Shoolbread, J. J. MacRitchie, J. J. Hamelin, H. S. Bissell, A. B. Moffat, V. B. Cartwright, A. B. Roberts, H. B. Stacpoole, G. W. Carleton, E. F. Niven, R. Paterson, and C. R. M. Pattison.

##### SPECIAL RESERVE OF OFFICERS.

Lieut. S. W. Hoyland to be Captain.

To be Lieutenants: M. J. Burns, C. Weir, J. A. H. Miller, W. Corner, W. Yeoman (from University of London Contingent, Officers Training Corps), S. C. Swinburne (from Edinburgh University Contingent, Officers Training Corps), and B. Mountain.

Capt. P. C. MacRae relinquishes his commission on account of ill-health.

Second Lieut. A. G. D. Gavin, M.C., resigns his commission to resume medical studies.

##### TERRITORIAL FORCE.

Major C. R. White to be temporary Lieutenant-Colonel.

Major A. Carless is seconded whilst holding a temporary commission in the R.A.M.C.

Capt. E. W. Holyoak to be seconded.

General Hospitals: Capt. V. W. Low, C.B., is restored to the establishment.

Sanitary Companies: Lieut. N. Gebble to be Captain.

Capt. (temp. Major) J. E. W. MacFall relinquishes his temporary rank on ceasing to command a Field Ambulance.

Capt. J. B. Sinson relinquishes his commission on account of ill-health.

*Supernumerary for Service with the Officers Training Corps.*

Lieut. (temp. Capt.) E. W. Walker to be Captain.

*Attached to Units other than Medical Units.*—Capt. R. Paterson relinquishes his commission on account of ill-health, and is granted permission to retain his rank and wear the prescribed uniform.

##### INDIAN MEDICAL SERVICE.

Surg.-Gen. Sir C. P. Lukis, K.C.S.I., Director-General, to rank as Lieutenant-General.

**CENTENARIANS.**—The *Times* states that on its front pages during 1916 the deaths of 321 persons who had reached the age of 90 and over were reported. Of these eight were over 100 (seven women and one man), the average age of the total number being a fraction over 93. The list includes 17 clerks in holy orders, and in 40 below the record of 1915.

## Correspondence.

"Audi alteram partem."

#### THE NOMENCLATURE OF "INTERNAL SECRETION."

*To the Editor of THE LANCET.*

SIR,—It must long have been evident to all those interested in the subject that our nomenclature concerning what we describe as "internal secretion" is extremely unsatisfactory. Professor Sir E. A. Schäfer in his recent book, "The Endocrine Organs," discusses the question, but unfortunately he does not improve matters, for he adheres to the indefensible word "endocrine," and introduces several other unnecessary terms. The word "endocrine," which Professor Schäfer and many other authorities employ, is supposed to be derived from *τύπω* (within) and *κρίνω* (I separate)—the compounded word being taken to mean "internally separating" when used as an adjective. But surely it is not classical to combine an adverb with a verb in Greek. The only adjective that can be formed from this combination is "endocrinic," and such words as "endocrinous" and "endocrine" are malformations. I think, also, that even "endocrinic," which I have been in the habit of using myself, is a poor word, and that we can find a better one.

Professor Bayliss and Professor Starling in 1903 introduced the term "hormone," derived from *ὅρμα* (I arouse); and they defined a hormone as a "chemical messenger." Professor Schäfer, however, objects to the word "hormone" being used indiscriminately for every internal secretion, for he considers that it implies an *exciting* agent only. His argument is that there are among the internal secretions not only exciting agents, which he would call "excitatory autocoids" (*αὐτός*=self, and *ἕκσος*=a medicinal agent or remedy) or "hormones," but also "inhibitory autocoids" or "chalones" (*χαλώ*=I make slack), as he would designate them.

It appears to me that Professor Schäfer's limitation of the word "hormone" is not really valid. In the first place, Professor Bayliss and Professor Starling are entitled to define their own term; and they have done so, as I think, correctly, although metaphorically. In the second place, since it is admitted that the word "hormone" implies "a substance that arouses," surely it can be taken as meaning a "chemical messenger," which *provokes either activity or inhibition*. The important point is that, in picturesque language, the agent in question is a chemical messenger, and therefore the terms "autocoids" and "chalones" are superfluous, even though they may be entirely correct in their meaning and derivation. We have, then, a descriptive and well-established noun "hormone," but we still require a noun for the hormone-making process and an adjective to indicate the hormone-making organs; consequently, I would suggest that the words "hormopoiesis" and "hormopoietic" respectively be added to our scientific vocabulary. Their derivation is obvious and, I think, unassailable. Further, they are in direct sequence from the term "hormone" and their meaning is quite clear. It is possible that these words have occurred to others, but I have never come across them.

I am glad to be able to say that both Sir Clifford Allbutt and Professor Starling entirely approve of the terms which I beg to suggest for general adoption.

I am, Sir, yours faithfully,

Liverpool, Dec. 28th, 1916.

W. BLAIR BELL.

#### THE PARLIAMENTARY REPRESENTATIVE OF DUBLIN UNIVERSITY.

*To the Editor of THE LANCET.*

SIR,—May we claim a small space in THE LANCET in order to urge upon its readers who are entitled to vote for a Parliamentary representative of Dublin University to record their votes at the forthcoming election for Sir Robert Woods, who is standing as a non-party candidate?

It would be idle for us to dwell upon the advantages that should accrue to the nation, and in particular to the medical

profession, by having in the House of Commons a distinguished scientific representative like Sir Robert Woods. It must be obvious to the medical graduates of Dublin University that the legal profession has had more than its share in the Parliamentary representation of the University, and a splendid opportunity is now offered whereby a change may be effected in this direction.

Owing, however, to the large number of medical graduates who are serving their king and country in the various theatres of the present war it will be extremely difficult to get into direct communication with many of the voters. We would, therefore, appeal to your readers, as this is a matter of urgency, to forward immediately to the appended address the addresses of any doctors of medicine of Dublin University who are known to them to be absent from their usual home addresses, so that proxies may be sent to such voters.

We are, Sir, yours faithfully,

A. FRANCIS DIXON,  
Professor of Anatomy; JAMES CRAIG,  
Honorary Secretaries.  
King's Professor of Practice of Medicine;  
24, Trinity College, Dublin, Dec. 30th, 1916.

### "SHELL SHOCK."

To the Editor of THE LANCET.

SIR.—It is interesting, and to me gratifying, to find that Captain E. Farquhar Buzzard has quite independently come to exactly the same conclusions as I expressed in my paper on the psychology of malingering and the functional neuroses published in your issue of Nov. 18th last. I hope those conclusions may now be generally recognised as indisputably correct.

"Shell shock" is a misleading and bungling term, covering several different disorders which were familiar before the war, viz.: (1) neurasthenia, due to lack of "ergogen" in the brain cells; (2) hysteria, or subconscious malingering following on emotional shock; (3) malingering of a purely conscious nature; and, lastly, (4) various combinations of the above.

It is, as Captain Buzzard points out, essential that such an analysis of "shell shock" cases should be made if they are to be satisfactorily treated, and it is well that the patients should recognise that they are not suffering from some new and wonderful disorder, but from common and curable diseases with which every physician has long been familiar. Appreciation of this fact will *per se* accelerate recovery.

I am, Sir, yours faithfully,

South Eaton-place, S.W., Jan. 1st, 1917. THOMAS LUMSDEN.

### LORD ROBERTS'S FIELD GLASSES: A RETROSPECT OF TWO YEARS' WORK.

To the Editor of THE LANCET.

SIR.—Soon after the outbreak of the war, my father, Lord Roberts, asked the public to lend their glasses for the use of the Army. After two years I think your readers may be glad to have some particulars of the result of his request.

Upwards of 26,000 glasses have been received, without reckoning those which, in pursuance of my father's suggestion, have been collected in Australia, the Malay States, and elsewhere, and issued forthwith to the local forces on their way to the seat of war. The instruments sent comprise every type, and have been classified and issued according to the needs of different units. Particularly useful have been the fine prismatic glasses sent which have been allocated to artillery and machine-gun units, according to their power; large mounted telescopes for batteries; deer-stalking telescopes for gunners and snipers, and good old-fashioned non-prismatic racing glasses for detection of the nationality of aircraft, locating snipers, signalling by disc, collecting wounded, and musketry instruction. I am indeed grateful for the way in which my father's appeal has been met. British people all over the world have given their best, recognising that, in spite of the fact that their glasses are on loan and that the organisation for their return has been arranged, the chances of loss are many, and that they may never get their glasses back.

When I think of the enormous numbers of good glasses sent it may seem ungracious to ask for more, but the demand

is still great. I am told that at watering places, and on racecourses and elsewhere, large numbers of glasses are still to be seen in private hands, and to the owners of these I would once more appeal. I should add that we have been entrusted by the Ministry of Munitions with the purchase of individual glasses from those who cannot afford to lend them, and that the address for sending glasses for either purpose is the same. Every good glass (except opera-glasses) and every telescope (except toys) is wanted for the service of the country.

Glasses should be addressed to the Manager of Lady Roberts' Field Glass Fund, National Service League, 72, Victoria-street, S.W.

I am, Sir, yours faithfully,

December, 1916.

ROBERTS.

### THE RESULTS OF FEEDING MICE WITH MOUSE CANCER.

To the Editor of THE LANCET.

SIR.—We are gratified to see in the report of the meeting of the Section of Pathology of the Royal Society of Medicine in your issue of Dec. 16th, 1916, that Professor S. G. Shattock and Mr. L. S. Dudgeon, as the result of experiments on feeding mice with tumours, suggest virtually the same hypothesis as that we published in THE LANCET of March 4th, 1916, as a deduction from the results of injecting sarcoma filtrate or feeding on streptothrix isolated from rat sarcoma. We there put forward the suggestion that the parasite is very small and enters into the cell, possibly the nucleus, from which it is set free by the mincing process. The streptothrix appears to be a parasite present in tumours, and in one cycle of its growth it may be really ultra-microscopic, but at present this is unproved. Certainly we have not, so far, succeeded in obtaining a differential stain to demonstrate the parasite in the tissues, in spite of its comparatively easy cultivation from them. We experienced the same difficulty again recently in a case of streptothrixosis in a cow. The streptothrix isolated from the tissues proved fatal to a guinea-pig in three weeks and it was recovered by cultivation from the guinea-pig tissues, but it could not be shown in the sections or films prepared from the tissues of either the cow or the guinea-pig.

Of course, the successful production of tumours in mice, by feeding with malignant material, has been observed and recorded at least once before, by Ford Robertson, in 1909.

We are, Sir, yours faithfully,

A. S. LEYTON.

University of Leeds, Dec. 23th, 1916.

H. G. LEYTON.

### SUPRARENAL HÆMORRHAGE IN CEREBRO-SPINAL FEVER.

To the Editor of THE LANCET.

SIR.—In THE LANCET of Dec. 23rd, 1916, Captain P. W. Maclagan and Captain W. E. Cooke describe some cases of cerebro-spinal fever characterised by rapid death and suprarenal haemorrhage. I should like to point out that Karakaschaff in 1904<sup>1</sup> described the case of a child who died from some other cause, and who had the medulla of both suprarenales calcified from old haemorrhage. While in hospital there were no signs of suprarenal disease. I myself have seen a specimen from a child whose symptoms were typical of suprarenal haemorrhage, yet here the damage was purely cortical. So also in Addison's disease. The rare cases of that condition which depend on "simple atrophy" show, if the atrophy has not gone too far, medulla surviving and cortex gone. It therefore appears, as I pointed out at the Pathological Society in January, 1914<sup>2</sup>, that suprarenal haemorrhage and Addison's disease are fundamentally the same.

If I am asked why the blood pressure drops, I can only say that I do not know, but I can also ask if we are justified in assuming that loss of blood pressure always depends on loss of adrenalin.—I am, Sir, yours faithfully,

S. G. SCOTT,

Netley, Hants, Dec. 31st, 1916. Temporary Lieutenant, R.A.M.C.

## Obituary.

JAMES LITTLE, M.D. & HON. LL.D. EDIN.,  
HON. M.D. DUB., &c.,

PAST PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND;  
REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF DUBLIN;  
HONORARY PHYSICIAN TO HIS MAJESTY THE KING  
IN IRELAND.

THE death occurred on Dec. 23rd of James Little, Regius Professor of Physic in the University of Dublin, and one of the best known physicians in the United Kingdom. For some months past he had suffered from a failing heart, but he insisted on attending the recent session of the General Medical Council, of which he was a Crown nominee. On his return home he was carried to bed, and passed quietly away.

James Little was born at Newry in 1837. He was educated at Cookstown Academy and at the Royal School, Armagh, and was apprenticed to his profession at Armagh. Later he studied medicine at the medical schools of Trinity College, Dublin, and the Royal College of Surgeons in Ireland and attended the practice of the Richmond Hospital. In 1856 he became L.R.C.S. Ire., and shortly afterwards took a medical appointment at Calcutta. He remained in India for three years, and on his return continued his medical studies. In 1861 he graduated in medicine in Edinburgh, and began to practise in Lurgan, but soon migrated to Dublin. He was elected physician to the Adelaide Hospital as long ago as 1864, and with this institution the whole of his professional life was closely associated.

In 1867 he became a Fellow of the Royal College of Physicians of Ireland, and subsequently served as registrar and examiner, being elected President in 1887.

Little's professional progress on arrival in Dublin was remarkably rapid. In 1868 he became lecturer on medicine in the Ledwich School, and in 1872 he was elected professor of medicine in the Royal College of Surgeons in Ireland. He resigned this chair in 1883, by which time his private practice had become very great, though it was not until 1898 that the resignation by Sir John Banks of the Regius Professorship of Physic in the University of Dublin gave him his connexion with Trinity College, which lasted up to his death. For many years past he was one of the Crown nominees on the General Medical Council, and he was honorary physician to His Majesty the King in Ireland. He was a past-president of the Royal Academy of Medicine in Ireland, and of the Association of Physicians of Great Britain and Ireland. He was consulting physician to several Dublin hospitals—the Rotunda, Dr. Steevens', the Royal Victoria Eye and Ear, and of late years, since his resignation of the post of visiting physician, to the Adelaide Hospital.\*

In his earlier days he wrote occasional articles for the medical papers, and he was the author of two small books: "First Steps to Clinical Studies" and "Chronic Disease of the Heart." Of late years he wrote little. A man of great physical and mental vigour, Little was a remarkably hale man and youthful for his age until comparatively recently. In 1914 he lost his wife, and the bereavement grieved him sorely. Shortly afterwards the Dublin rising tried him further, for his house was in the thick of much of the fighting and was fired into repeatedly. The old man went out fearlessly to attend professional calls, but he knew that he did so at the risk of his life. Last summer his health broke down definitely; but he was determined to attend the winter meeting of the General Medical Council in London, from which he returned a dying man.

Our Dublin Correspondent writes:—

For more than a generation James Little occupied a unique position in Irish medicine. It was not only that he was the leading physician and the first consultant in Ireland, but his voice was regarded as representative, in a special sense, of the medical profession with us. He was our unofficial head. For many years he enjoyed by far the largest practice in the country, probably one of the largest in the kingdom. He won it early in life, and he held it, almost without competition, for many years. To some it seemed that he secured it too easily, but the view was held only by those who did not know him well enough to recognise the native ability and shrewdness of the man, his painstaking study of

his patients, and his marvellous command of his own experience. His method was clinical rather than pathological. He reasoned with marvellous memory from patient to patient, and his judgment seemed to be intuitive when it was based really on close observation. He was fortunate in retaining his freshness and receptivity of mind to old age, and he made generous use of younger men who were conversant with the newer methods of diagnosis or treatment. No leader was ever more considerate or generous to his younger colleagues in the profession, and there are not a few men now well established in medical practice in Ireland who owe much of their success to Dr. Little's early encouragement.

WILLIAM CAYLEY, M.D. LOND., F.R.C.P. LOND.,  
CONSULTING PHYSICIAN TO THE MIDDLESEX HOSPITAL, AND TO THE  
QUEEN'S HOSPITAL FOR CHILDREN, ETC.

By the death of Dr. William Cayley, which took place on Dec. 17th after a brief illness, British medicine has lost one of its wisest exponents, whose exceptional gifts and sterling qualities were less widely known than they deserved to be. He died a few days after attaining the age of 80 at his house at Richmond, which he had occupied since his retirement from practice about 15 years ago. He retained to the last a keen interest in the hospitals to which he had been attached, and it was as the result of a chill contracted whilst attending a committee meeting at one of them that his fatal illness developed.

William Cayley was born at Stamford, Lincolnshire, on Dec. 14th, 1836, being the fifth of six sons of the late Edward Cayley, a partner in the banking firm of Eaton, Cayley, and Co. of that town. The family traced its descent from Cornelius Cayley, fourth son of Sir William Cayley, of Brompton, Yorkshire, who was created a baronet by Charles II. in 1681. William Cayley survived all his brothers, two of whom obtained distinction—Sir Richard Cayley, Chief Justice of Ceylon, and Surgeon-General Harry Cayley, of the Indian Medical Service. He was educated at Shrewsbury, where he imbibed a love of the classics which he retained throughout his life. His medical education was received at King's College, London, whence he graduated at the University of London, and obtained the M.D. in 1861. He then, as was not unusual amongst English and American graduates, proceeded to Vienna, where there existed opportunities for clinical and pathological research under professors of worldwide reputation such as Skoda and Rokitansky. He was chiefly attracted to the study of pathology, and his first medical appointment after settling in London was that of demonstrator of morbid anatomy at the Middlesex Hospital, where his fellow-student, Robert Liveing, had been engaged for the past year as demonstrator of anatomy in succession to W. H. Flower. At that time there were on the hospital staff three other men who had been trained at King's College. Charles Murchison was the senior assistant physician and J. W. Hulke and George Lawson the two assistant surgeons. It was not until 1870 that Cayley became assistant physician, but he continued to superintend the post-mortem examinations for some years by himself. In 1867 this duty was shared by the medical and surgical registrars, the first holders of which were Cayley and Henry Arnott. Their reports for the two years they held these offices were, we believe, the first of the kind issued by any London hospital. In 1869 Dr. John Murray was appointed medical registrar and Mr. (now Sir) Henry Morris surgical registrar. In the medical school Cayley, in 1866, became joint lecturer on pathological anatomy with Mr. Sibley, in succession to Dr. Burdon Sanderson, who was made lecturer on physiology, a subject hitherto taught in connexion with anatomy. For two or three years he had also assigned to him a class of histology, whilst continuing to teach pathological anatomy, having in the latter subject as colleagues Mr. Arnott and Dr. Murray in succession. In 1869 he succeeded Dr. Spencer Cobbold as curator of the museum.

The year 1870 brought many changes in the personnel of the Middlesex staff. Dr. Murchison, who was now full physician and lecturer on medicine, with an established reputation as a clinical teacher, accepted, together with Mr. Arnott (recently appointed assistant surgeon), an invitation to join the staff of St. Thomas's Hospital, whose new and palatial buildings on the south bank of the river had just been completed. In the same year Dr. Burdon Sanderson left to fill the chair of practical physiology at University College. Dr. Robert Liveing became senior

assistant physician, Dr. Greenhow succeeding to the physiciancy vacated by Dr. Murchison, and first Dr. Cayley and then Dr. Murray became assistant physicians. On the resignation, in 1876, of Dr. Liveing, who had become physician in 1872, Dr. Cayley was promoted to the full staff, becoming senior physician on the death of Dr. Greenhow in 1876. He resigned office in 1901, within a few months of attaining the age-limit, and was appointed by the governors consulting physician. In the medical school he continued to lecture on pathological anatomy until 1876, when he succeeded to the lectureship in medicine, which he undertook for nearly 25 years. He devoted much time and labour to the affairs of the school, the increasing prosperity and extension of which were very gratifying to him, and he seldom missed, even for some years after his retirement, attending the October gatherings and annual meeting of the club, where an opportunity was given for reunion of those who had received their training at the hospital.

Besides his appointments at the Middlesex Hospital, Dr. Cayley was for 20 years physician to the London Fever Hospital and for about 15 years to the North-Eastern (now the Queen's) Hospital for Children. In 1892 he was made consulting physician to each of these institutions. He was elected a Fellow of the Royal College of Physicians of London in 1872. He held at various periods the offices of examiner, councillor, and senior censor, and in 1880 was selected to deliver the Croonian lectures. He took for his subject the Pathology and Treatment of Typhoid Fever, upon which his experience as physician to the London Fever Hospital entitled him to speak with authority. Those privileged to attend these lectures could not fail to have been impressed by the depth of knowledge and the cogency of reasoning they revealed. They were delivered, or rather recited, without a note, with steady fluency—a truly remarkable effort of memory—for they were packed full of details, which were given in ordered sequence without a break. The first lecture on etiology adduced striking facts in opposition to the possible and not infrequent independent or *de novo* origin of the disease, which was held so staunchly by Dr. Murchison; in the second lecture the pathology was discussed, and the clinical course of the fever lucidly explained, as well as the degenerative lesions produced by the pyrexial state; all leading up to the thesis advanced with overwhelming force in the third lecture of the value of antipyretic treatment, especially by the use of cold baths, as originally advocated by Currie, then set aside and forgotten until revived by Brand of Stettin in his treatment of the fever-stricken soldiers who were taken prisoners in the war of 1870. When, after Dr. Murchison's death, Dr. Cayley was entrusted with the editing of the third edition of that great physician's *magnum opus*, "The Continued Fevers of Great Britain," he was careful not to interfere with the arguments therein so amply developed in favour of the "pyrogenic" origin of typhoid, but was content with brief interpolated notes, which showed how readily the facts might bear another interpretation. The bacillus had not yet been discovered, and it was 20 years or more before the "carrier" doctrine shed light on the origin of many an obscure case; but Cayley felt sure of his ground and saw no reason to change it.

He wrote the articles on typhoid fever for Fowler's "Dictionary of Medicine" and Allochin's "Manual of Medicine," but otherwise did not contribute very freely to medical literature. The second number of the newly established *Middlesex Hospital Medical Journal* contains an interesting clinical lecture by him on Cirrhosis of the Liver, which may be taken as an example of his teaching and the bearing of pathological knowledge on clinical facts and treatment. When he was first appointed to the charge of the post-mortem room he joined the Pathological Society, as in those days every aspirant to the London world of medicine and surgery felt it incumbent to do. The society was then nearing the zenith of its fame, and its fortnightly meetings at the Royal Medical and Chirurgical Society's rooms in Berners-street were amongst the most interesting of such gatherings. Middlesex Hospital was fortunate in being within a stone's-throw of the meeting-place, and its members contributed many a specimen. Cayley was an active member, for, besides his own exhibits, he had many specimens referred to him for examination in which he made good use of his histological knowledge; and when the Morbid Growths Committee was founded he long retained

a seat on it. In this society he filled in turn the offices of medical secretary, treasurer, and Vice-President. He was one of the original members of the Clinical Society, the foundation of which, in 1867, apparently emanated from members of the Middlesex staff. Of the 128 original members only 7 or 8 now survive, and the society is merged in the Royal Society of Medicine.

Cayley also belonged to the Royal Medical and Chirurgical Society, and several of the papers contributed by him to these societies illustrate the bent of his mind, in regard to the treatment of conditions beyond the power of medicine to do more than alleviate. He was well aware that resort to surgical intervention in such cases was often but a last resource, but having made up his mind as to the nature of the case and its hopelessness from the medical standpoint he had the courage and boldness to turn to the surgeon for aid. Thus to the Clinical Society he contributed papers on cases of (1) gangrene of lung treated by incision; (2) intestinal obstruction relieved by gastro-enterotomy; (3) haemoptysis treated by induction of pneumothorax so as to collapse the lung; and (4) perforation of bowel in typhoid fever treated by washing out the peritoneal cavity and excising the perforation; and in the Transactions of the Royal Medical and Chirurgical Society will be found two papers by him: one of a case of gangrene of lung successfully treated by drainage, and the other of a case of thoracic aneurysm treated by the introduction of steel wire into the sac.

Cayley's quiet, reserved, and unassuming character, his unbounded kindness of heart, his freedom from envy or ambition, and the charitable disposition which never allowed him to utter a word of disparagement or criticism of others, even when, in the opinion of most men, such comment would seem to have been fully justified—these are some of the traits that endeared him to all who knew him. One of these writes to us as follows:—"His was, indeed, an exceptional nature, and one felt in his presence that he could thoroughly be relied on in any of the trials and emergencies of life." His love of botany and of the Alps led him year by year to spend his summer vacation with congenial companions tramping in Switzerland, or the Tyrol, or by the Italian lakes. He knew Switzerland by heart, and as a member of the Alpine Club he made many a hazardous ascent. Perhaps the worst thing he felt in growing old was that he was no longer equal to these expeditions. But he found solace in his books and his garden, where he cultivated the flowers that he loved the most, and when the call came to him he was prepared, nay even glad, to depart, for he had spent a long, happy, and contented life, and had placed all his great gifts at the service of humanity.

#### RICHARD BARWELL, F.R.C.S. ENG., CONSULTING SURGEON TO CHARING CROSS HOSPITAL.

By the death of Mr. Richard Barwell in his native city of Norwich, at the mature age of 90, the Royal College of Surgeons of England has lost its senior Fellow and Charing Cross Hospital a consulting surgeon.

Richard Barwell was educated at St. Thomas's Hospital, becoming M.R.C.S. in 1848 and Fellow in 1852. Thus he had outlived all his contemporaries and most even of his junior colleagues. He was appointed lecturer on anatomy at the medical school of Charing Cross in 1868 and assistant surgeon in 1855, his seniors being Hancock, late President of the Royal College of Surgeons of England, and Canton. In 1872 he became full surgeon, and from that date until his retirement in 1888 he led an active and strenuous life. A list of his contributions to the Transactions of the societies is evidence of his activity in various directions. In 1863 he published a work on the "Cure of Club-foot without Cutting Tendons," and in 1868 his work on "Lateral Curvature of the Spine" appeared, which reached a fifth edition in 1895. In 1880 he wrote on "Aneurysm of the Thorax and at the Root of the Neck," and in 1881 he published a "Treatise on Diseases of the Joints."

A paper which he read before the Royal Medical and Chirurgical Society in 1881, on Experience in Specimens of the Ox Aorta Ligature, attracted considerable attention. In it he pointed out that certain cases of aortic aneurysm might be benefited by deligation of the right carotid and subclavian arteries, and insisted upon the advisability of leaving

the inner and middle coats of the arteries tied in continuity, intact. To this end he advocated the use of a ligature which would not cut those tissues, and claimed that the ligature cut from the aorta of an ox and dried fulfilled the requirements. A remarkable case of hypertrophy of the right side of the face in a boy aged 7 was described by him in the Pathological Society's Transactions, vol. xxxii. The specimen is now in the Charing Cross Museum showing great enlargement of the tissues, including the bones, a specimen which, in the opinion of Professor A. Keith, is unique.

Mr. Barwell quickly appreciated the immense value of Lister's treatment, but owing to lack of opportunity he never fully mastered all the details, which during his life of active surgery were largely subjects of experiment. He therefore failed to obtain the results which later surgeons with fuller experience now regard as assured.

Mr. James Cantlie writes: "Mr. Barwell was endowed with a painstaking and original mind and one well calculated to deal with the mechanical disabilities due to paralysis of groups of muscles, such as occurs in club-foot, and the profession is to-day indebted to many expedients introduced by him in these afflictions. His enthusiasm found him visiting cripples' homes, workhouse infirmaries, homes for incurables, &c., in pursuance of a study which in his day was seriously neglected, and upon which he succeeded in directing the attention of the profession generally." It was due to a suggestion by Mr. Cantlie that he should ligature an artery with an artery that he evolved the idea of the ox aorta ligature, and it was as a consequence of this that the catgut ligature was evolved. As an expert in orthopaedic surgery Mr. Barwell took a high place. His lectures to students upon lateral curvature and its treatment were classics in their completeness, and showed an originality of thought and conception only equalled by the clever technical devices by which he brought his ideas into practice.

Among his many friends Mr. Barwell will be remembered as an enthusiastic fisherman and an ardent skater. He was one of the best-known figures at the skating club in the grounds of the Toxophilite Society in Regent's Park, and he maintained his devotion until late in life to these pastimes. Their pursuit contributed to his hale old age, for no one would imagine that his trim figure and almost boyish step and carriage belonged to a man approaching 90 years of age.

**DEATH OF BRIGADE-SURGEON ALEXANDER CAMPBELL McTAVISH.**—Honorary Brigade-Surgeon A. C. McTavish, Army Medical Department (retired), died at his residence at Kingswear, Devon, on Dec. 2nd last. The deceased qualified L.R.C.S. Edin. in 1858, and shortly afterwards entered the Army Medical Department, being attached to the 60th Rifles. In 1860 he went to the Madras Presidency, and in 1863 was thanked by the Commander-in-Chief for his services in connexion with the cholera epidemic at Thayet-Myo. Later he was at Calcutta, and in 1874 was attached to the 17th Lancers. He served for many years in India, being invalided home in 1880, when he retired from the service.

**THE LATE MR. W. J. BEST.**—William Jenner Best, whose death occurred rather suddenly at the age of 51, was the son of the late Dr. Palmon Best, J.P., of Louth, Lincolnshire. He was educated at Rugby and Cambridge, receiving his medical education at the London Hospital and University and King's College, London. For the past 27 years he practised at Louth, taking his father's practice when the latter retired some years ago. He was very popular among his numerous patients, as well as among his medical colleagues at Louth.

AN advanced course of lectures on infant care for nurses, midwives, voluntary health workers, mothers, &c., will be held, under the auspices of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy, from Jan. 8th to Feb. 15th, on Mondays, from 3 to 4 P.M., at 1, Wimpole-street (corner of Henrietta-street, Cavendish-square), and on Thursdays, from 3 to 4 P.M., at the St. Marylebone General Dispensary, 77, Welbeck-street, W. Among the lecturers announced are Mrs. Scharlieb, M.D., Dr. Amand Routh, Dr. Eric Pritchard, Mrs. Shepherd, M.B., Dr. F. Langmead, Lady Barrett, M.D., Dr. R. C. Jewesbury, Dr. H. C. Cameron, Dr. John D. Rolleston, Dr. David Forsyth, and Dr. J. Lawson Dick.

## The War.

### THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

#### Killed.

Major P. A. Lloyd-Jones, D.S.O., R.A.M.C., was educated at Cambridge and at St. Bartholomew's Hospital, London, and graduated in 1904. He shortly afterwards joined the R.A.M.C., being gazetted major in July, 1915, and held a staff appointment as Deputy Assistant Director of Medical Services. He received the Order of the Crown of Italy for rescue work during the Messina earthquake, and had seen service in the South African War.

#### Wounded.

Capt. M. H. Barton, R.A.M.C., attached Leicester Regiment.  
Lieut. T. G. H. Drake, R.A.M.C.  
Capt. V. N. Rich, R.A.M.C., attached Dorset Regiment.

### THE HONOURS LIST.

The following awards to medical officers are announced:—

#### K.C.B.

Surg.-Gen. H. R. Whitehead, C.B.

#### C.B.

Col. (temp. Surg.-Gen.) J. M. Irwin, late R.A.M.C.; Col. R. L. R. Macleod, A.M.S.; Col. G. Cree, C.M.G., A.M.S.; Col. A. R. Sutton, D.S.O., A.M.S.; Col. G. H. Barefoot, C.M.G., R.A.M.C.; Temp. Col. T. Sinclair, A.M.S.; Lieut.-Col. E. T. F. Birrell, C.M.G., R.A.M.C.; Col. H. S. Birkett, Canadian A.M.C.; Col. J. A. Roberts, Canadian A.M.C.

#### K.C.M.G.

Surg.-Gen. R. W. Ford, C.B., D.S.O.; Col. M. P. C. Holt, C.B., D.S.O., A.M.S.

#### C.M.G.

Col. T. Daly, R.A.M.C.; Col. W. L. Gray, R.A.M.C.; Col. F. R. Newland, A.M.S.; Col. H. T. Knaggs, A.M.S.; Col. H. I. Pocock, R.A.M.C.; Col. B. H. Scott, R.A.M.C.; Col. R. W. Wright, R.A.M.C.; Col. T. Du B. Whaite, R.A.M.C.; Col. F. J. Morgan, A.M.S.; Temp. Col. T. C. English, A.M.S.; Lieut.-Col. A. R. Aldridge, C.S.I., Res. of Off., R.A.M.C.; Lieut.-Col. (temp. Col.) J. D. Ferguson, D.S.O. R.A.M.C.; Lieut.-Col. S. H. Withers, R.A.M.C.; Lieut.-Col. (temp. Col.) F. R. Buswell, R.A.M.C.; Lieut.-Col. L. F. Smith, R.A.M.C.; Lieut.-Col. (temp. Col.) F. A. Symons, D.S.O., R.A.M.C.; Temp. Lieut.-Col. G. M. Holmes, R.A.M.C.; Temp. Lieut.-Col. H. L. Eason, R.A.M.C.; Lieut.-Col. A. Sutton, Australian A.M.S.; Lieut.-Col. E. C. Hart, Canadian A.M.C.

#### Brevet-Colonel.

Lieut.-Col. H. H. Norman, R.A.M.C.

#### Brevet-Lieutenant-Colonels.

Maj. G. Ormrod, R.A.M.C.; Maj. (temp. Lieut.-Col.) E. Ryan, D.S.O., R.A.M.C.

#### Distinguished Service Order.

R.A.M.C.—Capt. R. G. Archibald, empld. Egypt. Army; Capt. F. R. Armitage.

Lieut.-Col. M. H. Babington; Capt. (temp. Maj.) W. K. Beaman; Capt. F. A. Bearn, M.C., Spec. Res.; Maj. (temp. Lieut.-Col.) W. Bennett; Lieut.-Col. W. A. Benson; Capt. (temp. Maj.) R. E. Bickerton; Maj. (temp. Lieut.-Col.) E. B. Bird; Maj. R. B. Black, Res. of Off.; Lieut.-Col. (temp. Col.) R. J. Blackham, C.I.E.; Lieut.-Col. (temp. Col.) E. W. Bliss; Maj. (temp. Lieut.-Col.) J. H. Brunskill; Maj. (temp. Lieut.-Col.) R. A. Bryden.

Capt. H. M. Calder; Lieut.-Col. F. F. Carroll; Lieut.-Col. R. W. Clements; Lieut.-Col. H. Collinson; Maj. J. H. M. Conway; Capt. M. Coplands.

Maj. (temp. Lieut.-Col.) H. A. Davidson; Capt. D. Dickie; Capt. (temp. Maj.) G. H. Dive; Lieut.-Col. (temp. Col.) H. M. Dunn.

Capt. (temp. Maj.) G. B. Edwards; Lieut.-Col. O. W. A. Elsner; Maj. H. H. A. Emerson.

Maj. and Bt.-Lieut.-Col. (temp. Lieut.-Col.) F. G. Fitzgerald.

Maj. (temp. Lieut.-Col.) W. R. P. Goodwin.

Maj. W. Haig; Maj. (temp. Lieut.-Col.) T. E. Harty; Maj. (temp. Lieut.-Col.) W. J. S. Harvey; Lieut.-Col. F. Hawthorn; Lieut.-Col. H. Hewetson; Lieut.-Col. H. C. R. Hime; Maj. (temp. Lieut.-Col.) A. E. Hodder; Maj. (temp. Lieut.-Col.) C. W. Holden; Capt. F. D. G. Howell; Lieut.-Col. W. E. Hudleston; Maj. (temp. Lieut.-Col.) D. O. Hyde.

Maj. O. Ivvers; Lieut.-Col. E. T. Inkson, V.C.

Maj. J. T. Johnson.

Maj. (temp. Lieut.-Col.) H. B. Kelly.

Lieut.-Col. J. W. Langstaff; Temp. Maj. (temp. Lieut.-Col.) C. E. Ligertwood.

Maj. (temp. Lieut.-Col.) E. McDonnell; Capt. (temp. Maj.) D. F. Mackenzie; Maj. (temp. Lieut.-Col.) J. Mackinnon; Lieut.-Col. C. W. Mainprise; Temp. Capt. J. D. Marshall; Maj. J. St. A. Maughan; Maj. C. R. Millar; Temp. Capt. R. M. Miller; Lieut.-Col. E. M. Morphew.

Maj. S. L. Pallant; Temp. Capt. W. N. Parker; Capt. (temp. Maj.) T. H. Peyton; Lieut.-Col. (temp. Col.) C. E. Pollock; Lieut.-Col. (temp. Col.) H. V. Prynne; Capt. (temp. Maj.) W. B. Purdon, M.C.; Maj. L. M. Purser.

Lieut.-Col. W. Ransom; Maj. (temp. Lieut.-Col.) M. B. Ray; Maj. (temp. Lieut.-Col.) T. F. Ritchie; Lieut.-Col. H. S. Roch; Maj. (temp. Lieut.-Col.) A. M. Rose.

Temp. Capt. E. Scott; Lieut.-Col. (temp. Col.) D. D. Shanahan; Lieut.-Col. (temp. Col.) J. P. Silver; Maj. J. O. Summerhayes.

Lieut.-Col. A. G. Thompson; Maj. C. G. Thomson; Maj. L. V. Thurston.

Lieut.-Col. A. A. W. Watson; Lieut.-Col. (temp. Col.) B. Watts; Capt. (temp. Lieut.-Col.) G. T. Willan, H. C. Fd. Amb.; Maj. (temp. Lieut.-Col.) M. G. Winder; Maj. (temp. Lieut.-Col.) B. F. Wingate; Maj. R. N. Woodley; Capt. (temp. Maj.) W. G. Wright.

Temp. Capt. W. A. Young.

A.M.S.—Lieut.-Col. (temp. Col.) C. W. Profeit; Lieut. (temp. Col.) P. W. Sargent.

R.N. Division.—Staff-Surg. C. E. C. Stanford, R.N.

Australian A.M.C.—Lieut.-Col. G. W. Barber; Maj. J. E. Dods, M.C.; Maj. H. K. Fry; Lieut.-Col. (temp. Col.) C. H. W. Hardy, V.D.; Maj. A. H. Marks; Lieut.-Col. J. H. Phipps; Lieut.-Col. T. G. Ross; Lieut.-Col. C. G. Shaw; Lieut.-Col. J. B. St. V. Welch.

Canadian A.M.C.—Temp. Col. A. E. Snell; Lieut.-Col. W. Webster; Lieut.-Col. R. P. Wright.

New Zealand M.C.—Lieut.-Col. D. W. W. Murray.

South African M.C.—Temp. Maj. M. S. Power.

#### Military Cross.

R.A.M.C.—Temp. Capt. W. Ainslie.

Temp. Capt. D. Bell; Temp. Capt. F. G. Bell; Temp. Capt. J. F. Bourke; Temp. Capt. H. Boyers; Capt. R. Burgess; Temp. Capt. G. B. Burwell.

Capt. F. S. Carson; Capt. C. Cassidy, empld. Egypt. Army; Temporary Capt. A. B. Cheves; Capt. A. G. Clark, Spec. Res.; Capt. T. C. Clarke; Capt. H. G. Crawford, Spec. Res.; Temp. Capt. D. E. Crosbie; Capt. A. G. Cummins, empld. Egypt. Army.

Temp. Capt. W. E. David; Capt. D. Davidson; Capt. D. Dongal, Spec. Res.; Capt. T. I. Dun, Spec. Res.; Temp. Capt. J. L. Dunlop.

Capt. C. D. Edwards; Temp. Capt. E. Evans.

Capt. T. G. Fleming, Spec. Res.; Temp. Capt. C. Y. Ford; Temp. Capt. D. T. Fraser; Capt. J. Fraser, Spec. Res.; Temp. Capt. A. Fullerton.

Capt. W. G. Galwey; Capt. J. G. Gill.

Temp. Capt. D. H. Hadden; Capt. G. H. Haines, Spec. Res.; Temp. Capt. H. P. Hamilton; Temp. Capt. G. F. Hardy; Capt. W. T. Hare, Spec. Res.; Capt. W. C. Hartgill, Spec. Res.

Capt. R. L. Impey, Spec. Res.

Capt. G. G. Johnstone.

Capt. T. J. Kelly, Spec. Res.; Temp. Capt. M. B. King.

Capt. G. Q. Lannane; Temp. Lieut. J. W. Littlejohn; Temp. Capt. A. L. Lockwood; Capt. W. E. C. Lunn.

Temp. Capt. E. L. Mackenzie; Temp. Capt. W. Macleod; Temp. Capt. A. Malseed; Temp. Capt. J. C. Matthews; Temp. Capt. G. R. D. McGeagh; Temp. Capt. A. F. Menzies; Temp. Capt. K. E. Millan; Temp. Capt. F. J. Morris; Capt. G. T. Mullally, Spec. Res.

Capt. F. J. S. Ney.

Temp. Lieut. W. L. Partridge; Temp. Lieut. M. G. Pettigrew.

Temp. Capt. A. B. Raffle; Temp. Capt. A. Richmond.

Capt. G. Scott; Capt. J. A. C. Scott; Capt. F. R. S. Shaw, Spec. Res.; Temp. Capt. G. M. Shaw; Capt. H. D. Smart; Capt. W. M. Snodgrass, Spec. Res.; Temp. Capt. W. N. Soden; Capt. L. B. Stott; Temp. Lieut. D. C. Suttie.

Capt. G. P. Taylor; Temp. Capt. F. R. Thornton.

Temp. Capt. B. W. Wibberley; Temp. Capt. D. L. Williams; Capt. M. J. Williamson; Temp. Capt. I. S. Wilson; Capt. J. H. Wood.

Temp. Capt. J. M. Young.

Australian A.M.C.—Capt. J. Bentley; Capt. J. B. Birch; Capt. A. E. Colvin; Capt. E. M. Fisher; Capt. J. T. Jones; Capt. C. B. Metcalfe.

Canadian A.M.C.—Capt. A. A. Drinnan; Capt. F. W. Lees; Capt. R. M. Luton; Capt. J. E. McAskill; Capt. W. F. Nicholson; Capt. (acting Maj.) P. Poisson; Capt. W. D. S. Rorison.

Egyptian A.M.C.—El Yuzbashi (Capt.) Musa Khouri Zakharis (Effendi); El Yuzbashi (Capt.) Nasralla El Burgi (Effendi).

New Zealand A.M.C.—Hon. Capt. G. Sandham.

Also the following in connexion with the Battle of Jutland:—

#### Distinguished Service Order.

Fleet-Surg. Ernest Alfred Penfold, R.N.

Was in the fore medical distributing station when a heavy shell burst just outside, killing and wounding many. He was knocked down, bruised, and shaken, but personally assisted in the removal of the wounded and tended them with unremitting skill and devotion for 40 hours without rest. His example was invaluable in keeping up the morale of the wounded and of the medical party under very trying conditions, the shell having destroyed instruments, dressings, &c.

And the following in connexion with the Tanganyika Flotilla:—

#### Distinguished Service Cross.

Surg. Hether McCormack Hanschell, R.N.

The comparative immunity from sickness enjoyed by the members of the expedition was due to the unremitting care bestowed by Surgeon Hanschell on the health of the personnel and on the sanitary state of the camps and vessels.

In the Indian list of New Year's honours for war services the following awards are recorded:—

C.B.—Inspector-General J. C. B. Maclean, R.N. (retired).  
C.I.E.—Lieut.-Col. J. G. Hoyle, I.M.S.; Dr. M. Y. Young, medical officer at the Oil-fields, Persian Gulf.

#### MENTIONED IN DESPATCHES.

The name of Fleet-Surgeon Alfred James Hewitt, R.N., is mentioned, and he is noted for accelerated promotion, "in recognition of the conspicuous gallantry and very exceptional professional ability which he displayed as medical officer of H.M.S. *Pegasus* when that ship was sunk by the *Königsberg* in September, 1914."

#### THE SOMME CAMPAIGN.

In a thrilling despatch from General (now Field-Marshal) Sir Douglas Haig, G.C.B., Commander-in-Chief of the British Forces in France, describing the several phases of the Somme campaign, tribute is paid to the valuable work of the medical services—

The losses entailed by the constant fighting threw a specially heavy strain on the Medical Services. This has been met with the greatest zeal and efficiency. The gallantry and devotion with which officers and men of the regimental medical service and field ambulances have discharged their duties is shown by the large number of the R.A.M.C. and Medical Corps of the Dominions who have fallen in the field. The work of the Medical Services behind the front has been no less arduous. The untiring professional zeal and marked ability of the surgical specialists and consulting surgeons, combined with the skill and devotion of the medical and nursing staffs, both at the casualty clearing stations in the field and the stationary and general hospitals at the base, have been beyond praise. In this respect also the Director-General has on many occasions expressed to me the immense help the British Red Cross Society have been to him in assisting the R.A.M.C. in their work.

The health of the troops has been most satisfactory, and during the period to which this despatch refers there has been an almost complete absence of wastage due to disease of a preventable nature.

A long list of names of officers and men deserving of special mention accompanies this despatch, and the names of the medical officers included will be given in THE LANCET.

#### OBITUARY OF THE WAR.

##### ALBERT GROENWALD, M.C.,

CAPTAIN, SOUTH AFRICAN MEDICAL CORPS.

Captain A. Groenwald, of the South African Medical Corps, died at the Johannesburg General Hospital on Nov. 11th last, after having been invalided back to the Transvaal from German East Africa, where his distinguished services won him the Military Cross. The funeral took place with military honours on Nov. 13th, and among those present were Mrs. Louis Botha, and Captain Brebner representing General Botha. The South African Railways and Harbours Corps provided the firing party, and the pall-bearers were Captains of the South African Medical Corps.

##### CHARLES HUMPHRY GOW, B.A. CAMB., M.R.C.S. ENG., TEMPORARY SURGEON, ROYAL NAVAL DIVISION.

Surgeon C. H. Gow, who was killed in action on Nov. 13th last at the age at 25, was the only son of the Rev. Henry Gow, of Rosslyn Hill Chapel, London, N.W., and nephew of Dr. W. J. Gow. Educated at Wyggeston School,

Leicester, Westminster School, and Emmanuel College, Cambridge, he was completing his medical study at St. Bartholomew's Hospital when war broke out and he enlisted as a surgeon-probationer, serving for nine months on a destroyer. He then returned home to complete his medical qualification, after which he at once became surgeon in the Naval Division, serving at Gallipoli, Salonica, and France. Surgeon Gow's commanding officer wrote of him as an upright, honest, and fearless man. During his short life he gave evidence of qualities which would have carried him far.

#### DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

G. D. Massy, London Regiment, elder son of the late Lieutenant-Colonel G. Massy, I.M.S., retired.  
Second Lieut. B. Hincks, King's Royal Rifle Corps, youngest son of Dr. T. S. H. Hincks, of Hay, Hereford.  
Private F. A. Hobart, Argyll and Sutherland Highlanders, youngest son of the late Dr. N. J. Hobart, of Cork.  
Second Lieut. R. L. L. Caunter, Gloucester Regiment, younger son of Dr. R. L. Caunter, of Brewood, Staffs.  
Second Lieut. N. M. H. Atkinson, only surviving son of Dr. T. R. Atkinson, of Chadwell Heath, Essex.  
Corporal F. Rendall, The Buffs, second son of Dr. W. Rendall, late of Maiden Newton, Dorset.

We are pleased to learn from Dr. Harry P. Major that Lieut. Cyril B. Major is officially reported as "Missing" only, and not as having fallen, as recorded in THE LANCET of Dec. 23rd, 1916. It is presumed that he has been taken prisoner.

#### CANADIAN ARMY MEDICAL SERVICE.

The official report of the Special Board of Inquiry appointed to investigate the charges brought against the Canadian Army Medical Service has been published, and by it the Service has been cleared in a most welcome manner of accusations which originated from official sources and had therefore to be seriously considered. Last summer the Canadian Minister of Militia, Sir Sam Hughes, appointed Colonel H. A. Bruce Special Inspector-General of the Canadian Army Medical Service, with the duty to report on the medical work of the Canadian Expeditionary Force. Colonel Bruce and a small committee thereupon drew up a drastic indictment of the Canadian Army Medical Service, recommending complete reorganisation of the Service, and attributing considerable blame to the Director of the Service, Surgeon-General Carleton Jones. The report of Colonel Bruce's Committee proposed the concentration of Canadian sick and wounded in Canadian hospitals, and suggested that the British V.A.D. were unsuitable for the care and treatment of Canadian soldiers. Surgeon-General Carleton Jones replied to the indictment of Colonel Bruce's Committee, but Sir Sam Hughes delivered an inaccurate and mischievous address at Toronto in which he adopted, apparently, the opinions of Colonel Bruce and his co-workers. This speech caused the most poignant grief and anxiety in Canada, as it conveyed the impression that the Canadian wounded were badly treated in British hospitals.

Sir Sam Hughes having resigned his office at the request of the Canadian Premier, he was succeeded by Sir George Perley, who at once instituted a strong Special Board of Inquiry into the findings of Colonel Bruce's Committee, with Surgeon-General Sir William Babtie as president. The new Board, in a report dated Dec. 21st, while accepting some of the recommendations made by Colonel Bruce's Committee upon the work and constitution of Medical Boards, is on greater matters at absolute variance with that Committee. The Board entirely disagrees with the suggestion that the Canadian Army Medical Service should be dissociated from the British service and that Canadian sick and wounded should be concentrated in Canadian hospitals. The Board finds that the V.A.D. hospitals are well run and well cared for, and that the criticisms of these institutions as inefficient and expensive were incorrect and unjust. The work of Surgeon-General Carleton Jones and that of his staff is praised by the Special Board of Inquiry, the Director of the Canadian Army Medical Service being especially commended for hard work, tact, and zeal.

Sir William Babtie's Board, in preparing its report, has not only taken into account the evidence submitted to it, but has incorporated into some of its recommendations its own know-

ledge of conditions so far as they affect the efficiency of the Canadian Army Medical Service. The report is thus rendered additionally valuable, as in this way the reasons are forthcoming for the dissent of the Board from the findings of Colonel Bruce's Committee, and its strong support of the Director of the Service. The report shows that, while special hospital establishments were provided for Canadian sick and wounded soldiers up to February, 1916, the pooling of hospital service and administration was later made necessary by the conditions of the war, and the economy of the existing method is demonstrated by figures. The policy attributed by the Board to Colonel Bruce of a separate medical administration for Canadian soldiers "would have prevented the use of Canadian Medical Units in the Mediterranean, because Canadian troops did not happen to be employed in that theatre of the war, and the sending of Canadian hospitals to Paris for the use of the French sick and wounded." The fact that Canadian soldiers have arrived in England from Canada who are medically unfit is attributed by the Board to inexperience of recruiting matters in Canada, a situation which might have secured protest from the Director of the Medical Service.

Dr. Ernest W. White, emeritus professor of psychological medicine, King's College, London, has been appointed honorary consultant in mental diseases to the Western Command, with the temporary rank of Major, Royal Army Medical Corps.

## Medical News.

**UNIVERSITY OF LONDON.**—The Graham Legacy Committee have elected Sir Seymour Sharkey, M.D., to be their chairman for the remainder of the year 1916-17. The University Medal at the M.B., B.S. Examination for internal and external students, October, 1916, has been awarded to Graham Selby Wilson, of Charing Cross Hospital. —The Senate will proceed shortly to an appointment to the Gilchrist Studentship for Women, which is of the value of £100, tenable for one year by a graduate of the University who is prepared to take a course of study in an approved institution in preparation for some profession. Candidates must have graduated in honours in the University of London, and must be of not more than three years' standing from their first graduation.—The third ordinary general meeting of the University of London Club, Limited, was held at the Club House on Dec. 14th, 1916. Major A. M. H. Gray was elected a member of the committee.

At examinations held recently the following candidates were successful:—

**SECOND EXAMINATION FOR MEDICAL DEGREES, PART I.**  
Abbas Yousef Amer, King's College; Marjorie Muriel Sibley Bartlett, London (Royal Free Hospital) School of Medicine for Women; Arthur Bearblock, University College; Dorothy Bellows and Hylda Catherine Briscoe, London (Royal Free Hospital) School of Medicine for Women; Eila Marianne Britten, Rhodes University College, Grahamstown; Egbert Avery Lennox Crichtow, King's College; Alfred Henry Gerald Down, University College; Pinkus Joseph Freilich, King's College; Edward Gallop, St. Bartholomew's Hospital; Frank Heber and Donald Hunter, London Hospital; Margaret Gray Jones, London (Royal Free Hospital) School of Medicine for Women; Carol Pinson Lake, University College, Exeter; Mary Michael, London (Royal Free Hospital) School of Medicine for Women; James Victor Alexander Simpson, Middlesex Hospital; Dorothea Compton Wigfield, London (Royal Free Hospital) School of Medicine for Women (distinction); and David Hardy Williams, London Hospital.

**M.D. EXAMINATION.**  
**Branch IV.**, *Midwifery and Diseases of Women.*—Charles Frank Schuler, B.S., St. Thomas's Hospital.  
**Branch V.**, *State Medicine.*—Ethel Mary Minett, B.S., London (Royal Free Hospital) School of Medicine for Women; Laura Gertrude Powell, B.S., University College, Cardiff, and London (Royal Free Hospital) School of Medicine for Women; and Robert Heywood Wilshaw, B.S., Victoria University of Manchester and University College and Guy's Hospitals.

**M.S. EXAMINATION.**  
**Branch I.**, *Surgery.*—Charles Jennings Marshall, M.D., Charing Cross Hospital (University Medal).

**UNIVERSITY OF CAMBRIDGE.**—At examinations for Medical and Surgical degrees held during Michaelmas term, 1916, the following candidates were successful:—

**FIRST EXAMINATION** (October, 1916).  
**Part I., Chemistry.**—I. R. Paterson, King's; C. V. Patrick, Calus; C. M. Pollock, Trinity; J. H. Porter, Downing; W. Shaw, St. John's; H. Spibey, Downing; and T. M. Thomas, Calus.  
**Part II., Physics.**—J. H. H. Gough, Corpus Christi; I. R. Paterson, King's; C. V. Patrick, Calus; C. M. Pollock, Trinity; W. Shaw, St. John's; H. Spibey, Downing; and T. M. Thomas, Calus.

*Part III., Elementary Biology.*—I. R. Paterson, King's; C. V. Patrick Caius; and W. Shaw, St. John's.

FIRST EXAMINATION (December, 1916).

*Part I., Chemistry.*—S. J. Astbury, Sidney Sussex; G. J. V. Crosby, Christ's; A. Grant, Trinity; K. T. Liang, Caius; L. R. W. Price, Sidney Sussex; A. E. Slater, B.A., Christ's; and F. B. Sudbury, Caius. Women: J. R. Batten, Newnham; and D. A. D. Cropper, Girton.

*Part II., Physics.*—S. J. Astbury, Sidney Sussex; A. Grant, Trinity; J. H. Jones, non-Collegiate; K. T. Liang, Caius; J. H. Porter, Downing; L. R. W. Price, Sidney Sussex; F. B. Sudbury, Caius; E. R. C. Walker, Emmanuel. Women: J. R. Batten, Newnham; and D. A. D. Cropper, Girton.

*Part III., Elementary Biology.*—K. T. Liang, Caius; J. H. Porter and F. Skelton, Downing; A. E. Slater, B.A., Christ's; H. Spibey, Downing; and F. B. Sudbury, Caius. Women: J. R. Batten, Newnham.

SECOND EXAMINATION (October, 1916).

*Part II., Pharmacology and General Pathology.*—W. E. H. Banks, Clare; F. J. Bennett, B.A., Peterhouse; C. B. Clarke, Catharine; E. W. M. Dendy, B.A., Trinity; H. B. Dodwell, B.A., Emmanuel; C. Duncombe, Downing; H. V. Edwards, Trinity; L. E. Frazer, Caius; L. P. Garrad, King's; A. D. Haydon, B.A., Caius; N. S. Hewitt, B.A., and F. R. G. Hiet, B.A., Sidney Sussex; R. Hilton, Corpus Christi; H. G. G. Jeffreys, B.A., Trinity; T. A. Jones, Emmanuel; C. F. McLean, King's; E. Miller, B.A., St. John's; W. H. Palmer, Sidney Sussex; J. L. Potts, Caius; F. W. Putnam, B.A., Emmanuel; F. G. Spear, Christ's; B. W. Thompson, B.A., King's; Y.-S. Wan, St. John's; and F. G. Wood, B.A., Jesus.

SECOND EXAMINATION (December, 1916).

*Part I., Human Anatomy and Physiology.*—G. F. Abercrombie, Caius; S. T. Barrett, B.A., St. John's; T. L. Bonar, Caius; W. Breakall, Sidney Sussex; P. J. Briggs, B.A., Christ's; W. R. Carling and F. O. Coze, Emmanuel; A. do Souza, B.A., Downing; V. N. Fenton, Queens'; S. G. Galstaun, B.A., Trinity; F. B. Hobbs, Sidney Sussex; G. W. Karunaratne, Clare; P. B. Kittel, Emmanuel; G. S. Need, B.A., St. John's; J. A. P. Shaw, Trinity; J. V. Sparks, St. John's; S. D. Sturton, Emmanuel; H. Tagoe, Christ's; and H. B. Yates, Downing.

THIRD EXAMINATION (December, 1916).

*Part I., Surgery and Midwifery.*—D. J. Batterham, B.A., Caius; D. C. Beaumont, B.A., Christ's; A. D. Haydon, B.A., Caius; B. B. Jarek, Trinity; G. M. Kendall, B.A., St. John's; G. L. Maulle, B.A., Christ's; V. O. Pennell, M.A., Pembroke; D. W. R. Richardson, B.A., Caius; and F. A. Williamson, B.A., Queens'.

*Part II., Medicine, Pathology, and Pharmacology.*—C. H. Crawshaw, B.A., Christ's; H. W. Featherstone, B.A., Trinity; A. D. Haydon, B.A., Caius; H. G. G. Jeffreys, B.A., Trinity; G. M. Kendall, B.A., St. John's; C. F. Mayne, B.A., Caius; A. Orr-Ewing, B.A., Pembroke; A. A. Prichard, M.A., Clare; and T. S. Thirard, Trinity.

PUBLIC HEALTH IN BELFAST.—Our Belfast Correspondent writes: In 1916 there was a reduction of nearly 50 per cent. in the number of cases of scarlet fever notified in the previous year. On the other hand, while in 1915 only 49 cases of typhoid fever were notified, in 1916 the number rose to 123, a large proportion of the cases being in the Ballymacarrett district. Nothing has yet been done for maternal and child-welfare, but it is said a scheme is now prepared for the approval of the Local Government Board of Ireland.

DONATIONS AND BEQUESTS.—By the will of the late Miss Schaw the Glasgow Royal Infirmary has received £100,000. Other Glasgow medical institutions will receive a share of the £500,000 left by the testatrix.—The Clayton Hospital and Dispensary will receive £1000 under the will of the late Major W. H. Charlesworth, of Wakefield.—The Middlesex Hospital Cancer Ward for Women and the New Hospital for Women, Euston-road, will very considerably benefit under the will of the late Mr. Mudford, formerly editor of the *Standard*.—The late Mr. Henry Jones, of Branksome Park, Bournemouth, left by will £1000 to the Hospital for Incurables, Putney.—Colonel Thomas Edgar Jobling, of Bebside, Northumberland, has bequeathed £2000 each to the Royal Infirmary, Newcastle-on-Tyne, and the Fleming Memorial Hospital, Newcastle-on-Tyne; £1000 each to the Hospital for Incurables, Newcastle-on-Tyne, the Royal Victoria Asylum for the Blind, Newcastle, the Northern Counties Asylum for the Deaf and Dumb, the Home for Destitute Crippled Children, Gosforth.

UNIVERSITY OF MALTA: CONFERMENT OF HONORARY DEGREES.—On Dec. 16th, 1916, in the Aula Magna of the University of Malta, the degree of Doctor of Medicine, *honoris causa*, was conferred upon Colonel C. A. Ballance, C.B., M.V.O., A.M.S.; Colonel W. Thorburn, C.B., A.M.S.; Colonel A. E. Garrod, C.M.G., A.M.S.; and Colonel H. H. Tooth, C.M.G., A.M.S. This was the first conferment of honorary degrees under the provisions of a new statute, and as the Rector of the University, the Hon. Professor E. Magro, pointed out, it was the highest honour that the University was able to give. In describing the claims to such recognition of the new graduates of the University of Malta, Lord Methuen, the Governor of the Island, referred also to the services of Colonel G. L. Gulland, Colonel Charters Symonds, and Colonel Purves Stewart during their stay in Malta, and to the work of Colonel A. E. Barker, who, to the deep regret of all, gave his life for his country in Salonika. Sir Alfred Keogh, Director-General of the Army Medical Service, said his Excellency, bestowed an inestimable boon on Malta when he sent such able members of the medical profession to assist in the hospital work of the island.

THE CERTIFICATION OF SENILE PERSONS AS INSANE: A SCOTCH CONFERENCE.—In his last annual report Dr. C. J. Shaw, medical superintendent of the Royal Asylum, Montrose, deprecated the certification as insane and the transference to asylums of old people in whom mental symptoms were but the result of physical weakness and restlessness was only a terminal symptom. With adequate nursing and observation at night these old people could safely remain at home. A conference of representatives of parish councils recently took place at Montrose to discuss this question and a committee was appointed to deal with it.

## Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

ALCOCK, ARNOLD, M.D. Lond., has been appointed Honorary Surgeon to the Gloucestershire Royal Infirmary and Eye Institution.

BOWER, H. E., M.D., C.M. Edin., Medical Officer of Health to the Runcorn Rural District Council.

DUNDAS, GRACE H. G., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., F.R.C.S.I., Medical Officer under the Child-Welfare Scheme of the Leith Town Council.

JONES, E. LLOYD, M.D., B.C. Camb., Demonstrator of Medicine at Cambridge University.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

BELFAST COUNTY BOROUGH MUNICIPAL SANATORIUM, Whiteabbey.—Temporary Resident Medical Superintendent. Salary at rate of £400 per annum, with board, &c.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Resident Medical Officer and House Surgeon for six months. Salaries £200 and £150 per annum respectively, with board, &c.

BOLTON INFIRMARY AND DISPENSARY.—Female Second House Surgeon. Also Female Third House Surgeon. Salaries £200 and £180 per annum, respectively, with board, &c.

BOURNEMOUTH, ROYAL VICTORIA AND WEST HANTS HOSPITAL.—House Surgeon for six months. Salary £200 per annum, with board, &c.

BRISTOL GENERAL HOSPITAL.—House Surgeon for six months. Salary at rate of £175 per annum, with board, &c.

BRISTOL, BEAUFORT WAR HOSPITAL, Fishponds.—Resident Surgical Officer. Salary £365 per annum, with board, &c.

CARDIFF, KING EDWARD VII'S HOSPITAL.—House Surgeon for six months.

CARDIFF, KING EDWARD VII. WELSH NATIONAL MEMORIAL ASSOCIATION.—Tuberculosis Physicians. Salary £500 per annum. Also Assistant Tuberculosis Physicians. Salary £350 per annum.

CARLISLE, CUMBERLAND INFIRMARY.—Resident House Physician. Salary £200 per annum; or fifth-year student, salary £100 per annum.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—Second House Surgeon. Salary £150 per annum, with board, &c.

CHILDREN'S INFIRMARY, Cleveland-street, London, W.—Female Assistant Medical Officer. Salary £250 per annum, with residential allowances.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £200 per annum, with board, &c.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeons, Assistant Casualty Medical Officer, and House Physician, unmarried. Salary at rate of £60 per annum each, with board, &c.

HUDDERSFIELD COUNTY BOROUGH EDUCATION AUTHORITY.—Assistant School Medical Officer. Salary £350 per annum.

INVERNESS, NORTHERN INFIRMARY.—House Surgeon or Locum Tenens. Salary as arranged, with board, &c.

MANCHESTER COUNTY ASYLUM, Prestwich.—Locum Tenens. Salary £7 1s. per week, with board, &c.

NORTHAMPTON GENERAL HOSPITAL.—House Surgeon. Salary £150 per annum, with board, &c.

NOTTINGHAM AND MIDLAND EYE INFIRMARY.—Female House Surgeon.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Clinical Assistant in Out-patients' Department.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Physician and House Surgeon for six months. Salary £100 per annum, with board, &c.

QUEEN MARY'S HOSPITAL FOR THE EAST-END, Stratford.—House Surgeon.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Female Surgical Registrar.

ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, 234, Great Portland-street, W.—Resident Surgical Officer.

ST. GEORGE'S HOSPITAL, Hyde Park Corner, S.W.—Surgical Registrar. Salary £200 per annum.

SCOTTISH WOMEN'S HOSPITALS, 2, St. Andrew-square, Edinburgh.—Assistant Medical Officers for Serbian Unit in Russia. Also Assistant Surgeon for Serbian Unit in Macedonia. Salary at rate of £200 per annum, with board, &c.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £120 per annum, with board, &c.

SOUTH LONDON HOSPITAL FOR WOMEN, 103, South Side, Clapham Common, S.W.—Female House Physician for six months. Salary at rate of £100 per annum, with board, &c.

VENTNOR, ISLE OF WIGHT, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST ON THE SEPARATE PRINCIPLE.—Assistant Resident Medical Officer.  
VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—Honorary Dental Surgeon.  
WELSH METROPOLITAN WAR HOSPITAL, Whitchurch, near Cardiff.—Resident Medical Officer.  
WESTMORELAND SANATORIUM, Meathop, Grange-over-Sands.—Second Assistant Medical Officer. Salary £200 to £250 per annum, with board, &c.

THE CHIEF INSPECTOR OF FACTORIES, HOME OFFICE, LONDON, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Esher, Surrey; Lydbrook, Glos.; and Hull, Yorks.

## BIRTHS, MARRIAGES, AND DEATHS.

### BIRTHS.

ATKINSON.—On Dec. 24th, at Hoefield House, Carlisle-avenue, Plymouth, the wife of Surgeon C. H. Fairbank Atkinson, R.N.V.R., of a daughter.  
BIGGS.—On Dec. 1st, at York House, Blenkarne-road, Wandsworth Common, the wife of Major George Nixon Biggs, R.A.M.C.T., of a son.  
INGOLBY.—On Dec. 16th, at Lahore, India, the wife of Captain C. M. Ingolby, R.A.M.C., of a son.  
JONES.—On Dec. 30th, at Hillview, Grove Park, Kent, the wife of Captain Sydney H. Jones, R.A.M.C., of a daughter.  
LAPAGE.—On Dec. 9th, at 194, Wilmslow-road, Withington, Manchester, the wife of C. P. Lapage, M.D., Captain, R.A.M.C., T. (*à la suite*), of a son.  
MACMANUS.—On Dec. 31st, at The Cottage, Granville Park, Blackheath, the wife of Captain Desmond MacManus, R.A.M.C., of a son.  
PEACOCK.—At the Epsom Nursing Home, on Dec. 27th, the wife of W. Baly Peacock, M.R.C.S. Eng., L.R.C.P. Lond., of Bracklesham, Epsom, of a daughter (Joan Elizabeth).  
ROOKE.—On Dec. 24th, at Knole-road, Bournemouth, the wife of A. Basil Rooke, F.R.C.S., of a son.

### MARRIAGES.

ABRAHAM—CAKETT.—On Dec. 21st, at the Parish Church, Crowhurst, Sussex, Everard Cecil Abraham, Captain R.A.M.C., to Dorothy Trease Cackett, daughter of the late Edward and Beasie Cackett, of Canterbury.  
GORDON—POWER.—On Dec. 27th, in London, Hon. Lieutenant-Colonel Mervyn Henry Gordon, M.D., R.A.M.C., to Mildred Olive, daughter of the late Sir William Power, K.C.B., F.R.S.  
HARWOOD—PAIN.—On Dec. 31st, at St. Matthew's, Newington, Captain L. A. Harwood, R.A.M.C., to Lily Fanny, eldest daughter of Dr. and Mrs. Pain, New Kent-road.  
SCOTT—BURNS.—On Dec. 30th, 1916, very quietly, at S. Mary's, Finchley, Eric Arnold Scott, temporary Captain, R.A.M.C., only son of Albert G. Scott, Glenroy, Seymour-road, Finchley, to Margaret Jessie Burns (Madge), daughter of the late J. B. Burns, of Rugeley.

### DEATHS.

BARWELL.—On Dec. 27th, at Norwich, Richard Barwell, F.R.C.S., Consulting Surgeon to Charing Cross Hospital, aged 90 years.  
ORANGE.—On Dec. 31st, at Marina-court, Bexhill, William Orange, C.B., M.D., formerly Superintendent of Broadmoor Asylum, aged 83.  
SALTER.—On Dec. 21st, at Higher Summerlands, Exeter, John Reynolds Salter, M.R.C.S., L.S.A., in his 91st year.  
SHILLITO.—On Dec. 23rd, at Ardverns, 3, Richmond-gardens, Bournemouth, Buxton Shillitoe, F.R.C.S., late of 2, Frederick's-place, Old Jowry, E.C., in his 91st year.  
SMITH.—On Dec. 21st, at Dover House, Southsea, Henry Robert Smith, I.R.C.P. & S., aged 74 years.  
SUTHERLAND.—On Dec. 23rd, at 33, Trafford-road, Salford, Manchester, Wm. Leith Ireland Sutherland, M.B., C.M., aged 61.  
N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Other information which we have been accustomed to give in these "Readings" is withheld for the period of the war.

The following journals, magazines, &c., have been received:—American Medicine, Clinical Medicine, Medical Review of Reviews, Journal of the Missouri State Medical Association, Mercy and Truth, Medical Journal of South Africa, Archives of Internal Medicine, Indian Journal of Medical Research, Archives de Médecine et de Pharmacie Militaires, Prescriber, Dominion Medical Monthly, American Journal of Surgery, Medico-Legal Journal, Journal of Scottish Meteorological Society, Proctologist and Gastroenterologist, Journal of Nervous and Mental Diseases, Annali di Medicina Navale e Coloniale.

## Notes, Short Comments, and Answers to Correspondents.

### MILK IN THE DIET OF INFANTS.

To the Editor of THE LANCET.

SIR,—The letter of your correspondent "M.D., M.R.C.P." in THE LANCET of Dec. 30th, 1916, does not supply sufficient evidence to determine the method to be adopted of solving the problem he propounds. The phenomenon of milk causing retching may be due to one of two causes—an idiosyncrasy towards cow's milk or intense disgust. One instance of the former has come under my notice, though in a younger child. An infant, aged 7 months, was brought for advice on weaning, as any form of cow's milk—dried, peptonised, or merely dilute—gave rise to coryza, bronchitis, and an urticarial rash with digestive disturbance. This sequel to the taking of milk I personally verified, and the reaction to 3 ounces of milk was most striking.

Recollecting a case of idiosyncrasy to eggs published in your journal a few years ago, I adopted the line of treatment there used with success—that of producing toleration to minute quantities of the offending substance, and then gradually increasing the amount. Finding that a mixture of water, albumactin, and lactose caused no disturbance, a minute quantity of cream—5 minims to 3 ounces—was added and a feed of this was given once daily. As the slight disturbance caused gradually lessened the amount of cream was increased, and finally, after three months, the child was able to take a fair quantity of milk and weaning was accomplished.

I do not discuss what may have been the actual factor causing the intoxication or why this particular mixture was adopted at the outset of treatment. Disgust would seem to be the more probable cause in your correspondent's case. It is common for children to evince great repulsion towards certain foods, and if they are taken under compulsion retching and even vomiting may follow. Even more, I have met children who would announce that if a certain article of diet were forced upon them, they would be sick and they always carried out their threat. Frequently the hostility is only evinced towards one form of milk and may be overcome by presenting that food in other forms, as in soups, puddings, milk jelly, or flavoured with cocoa, for which purpose cocoa husks are useful, of which the devising will fall upon the ingenuity of mother and nurse.

It must be acknowledged that it is difficult to ensure a quart of milk being taken daily in these ways, and if it proves impossible the protein and fat content of the diet must be increased by allowing additional eggs and butter or by the use of one of the proprietary preparations, such as virol, the intake of fluid being kept up to the requisite amount by giving water to drink in place of milk. The arrangement and regulation of such a diet can only be undertaken by one having a personal knowledge of the child and able to keep the progress of events under observation, for no child which presents such difficulty in feeding can be fed on a rule-of-thumb method.

I am, Sir, yours faithfully,  
Upper Wimpole-street, W., Jan. 1st, 1917. DOUGLAS FIRTH.

### "INDEX DOSURINE CASE."

THE Anglo-French Drug Company, Limited, of Gamage Building, Holborn, London, E.C., have brought to our notice the "Index Dosurine Case," which is a compact pocket outfit for the testing of urine for sugar and albumin. It contains a series of ampoules filled with a convenient quantity of the sugar and albumin reagents. A small pipette and two test-tubes are also provided. Some small pellets which prevent the liquid from bumping when being brought to the boil are included in the outfit. This set reduces the testing of the urine for sugar and albumin to a very simple matter and will be very useful for bedside work. An ordinary candle-flame is sufficient for heating the fluids.

### PILEWORT.

To the Editor of THE LANCET.

SIR,—Can any of your readers kindly tell me something about the use of "pilewort"? Quite recently I have met persons suffering from haemorrhoids who informed me that they had used to their great relief a certain secret ointment. I have purchased a pot of this ointment, which I have reason to believe has "pilewort" as an essential ingredient. On application the ointment causes a numbing astringent sensation, slightly discomforting at first but quickly passing away.

According to Stedman's Medical Dictionary, "Wort—(A.S. Wyrt) a suffix in the popular names of many plants such as liverwort, lungwort, woundwort, &c.;

also means an infusion of malt." The distinctive botanical characters of the "worts" and their uses are described in "Potter's Cyclopaedia of Botanical Drugs and Preparations," second edition, by R. C. Wren, F.L.S., with additions by E. M. Holmes, F.L.S., but as I am only dealing specifically with "pilewort," I quote from this Cyclopaedia: "Pilewort—*Ranunculus Ficaria*, Linn., N.O. *Ranunculaceæ*. Syn.—Small Celandine, Lesser Celandine. Part used, herb. Action, astringent. As its name denotes, it is chiefly used for piles, for which it is almost a specific. Internally, the infusion of one ounce in a pint of boiling water is taken in wineglassful doses. Generally this is sufficient to cure most cases. Externally it can be used with advantage as an ointment applied locally night and morning." Then follows the distinctive botanical characters.

Now, Sir, it does appear to me that if these "worts" have any real medicinal properties, such as I believe the "pilewort" to have, why not add them to the Pharmacopœia, as many other remedies have from time to time been added to the "Book" containing the official list of medicines and compounds.—I am, Sir, yours faithfully,

FREDK. W. ALEXANDER,  
Medical Officer of Health, Metropolitan Borough of Poplar.  
Dec. 20th, 1916.

\*\* Pilewort ointment is still made, in part owing to the advocacy of Sir James Sawyer (*Birm. Med. Rev.*, May, 1901), though medicine has found the claims of the plant invalid. The botanical name is *Ranunculus ficaria*, but it was mentioned by John Gerard in his "Herball," published in 1597, as *Chelidonium minus*, or the "lesser celandine." Although it is a buttercup, and an entirely different plant from the greater celandine (the poppy order), the "lesser celandine" is the name that endures to-day, and Wordsworth under this name devoted a poem to the little flower. Culpeper in his "Herball" (about 1653) praises it, and within the last century it has been recommended in medicine in the following terms: "The leaves are antiscorbutic and the root reckoned a specific if beat into cataplasms and applied to the piles." But 50 years later we observe a change, as the editor of Lindley's works says: "Confident as are these assertions (those of Culpeper and others), yet the use of the plant is all but discontinued in the present day, medical practitioners properly looking for sounder principles than those derived from the doctrine of similitudes." The editor further states: "The trivial name of pilewort bestowed upon this plant from the structure of those tubercles (of the root) which show in small bundles of small tubers so like the shape of those excrencences which occur in the more distressing cases of piles that our forefathers who chose their medicines not from knowledge of the properties and qualities of plants, but from a kind of fancy as to Nature's external impress indicating the innate virtues, adopted it as a remedy for this malady." Pilewort flowers in early spring, and the roots form fasciculated knobs (hence the name *ficaria*, like figs).—ED. L.

#### THE QUESTION OF PROHIBITION.

To the Editor of THE LANCET.

SIR,—Fleet-Surgeon W. E. Home, in his letter in your issue of Dec. 23rd, 1916, advocates "closing all licensed houses till the war ends." How does he explain the hard fact that the heaviest beer-drinkers in Europe have, so far, proved themselves to be the bravest and most successful fighters in this war? In our victorious wars of the past, naval or otherwise, the British drank beer as much as anyone. Prohibition theories do not seem to square with the teachings of military history.

I am, Sir, yours faithfully,

H. N. ROBSON.  
Junior Constitutional Club, Piccadilly, W. Dec. 29th, 1916.

#### A MEDICAL PHILOLOGIST.

MEMBERS of the medical profession who are Esperantists, or who are interested in the auxiliary language which is receiving increased attention at the present moment owing to its utility as an instrument of social, professional, and commercial intercourse, will read with pleasure an interesting sketch of Dr. Zamenhof which appears in the *Times* of Dec. 30th, 1916, in the Russian Section. Dr. Zamenhof, the inventor of Esperanto, was born at Bialystok in 1859, and though physically delicate, his intellect developed quickly, for he was able to read and write well at the age of four. Having qualified in medicine, he specialised in ophthalmology, studying for this purpose at Vienna, and ultimately taking up practice in Warsaw in 1886. In the following year he published his first text-book of an international language under the pseudonym of Dr. Esperanto, one who hopes, a name which subsequently became attached to the language itself. The language gradually began to spread in Russia, Germany, Sweden, Poland, and France, but did not take root in Britain till 1902. In 1905 an Esperanto Congress was held

at Boulogne-sur-Mer, which was attended by delegates from all parts of the world, when the practicability of the language was clearly established. Other congresses have been held at Cambridge, Dresden, Barcelona, Washington, Antwerp, and Cracow, and in connexion with them Dr. Zamenhof has been made a Chevalier of the Legion of Honour, and received the Order of Isabella the Catholic, and many other distinctions. The author of Esperanto, who is now suffering from heart disease, devotes all his spare time to Esperanto, and has translated into that language many classics of the leading countries, as well as the whole of the Old Testament from the Hebrew original.

#### IRISH NURSES AND THE COLLEGE OF NURSING, LIMITED.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Dec. 16th the secretary of the College of Nursing, Limited, intending to correct a statement made by me in your previous issue, states that "on reference to the Memorandum and Articles of Association it will be seen that membership of the College is strictly limited to nurses who possess a certificate of proficiency in general [italics in original] nursing (medical and general), and it is the members who govern the College." I have been unable to verify the secretary's statement. Paragraphs 3(D) and 3(E) of the Memorandum of Association deal with the granting of "certificates of proficiency in nursing" and of "certificates of training and proficiency in nursing," do not use the word "general," which is italicised by Miss Rundle, nor do they describe the nursing as "medical and surgical." Moreover, Paragraph 3 (I) makes it clear that the Council is not to be limited in its giving of certificates by the terms of the preceding paragraphs. The first paragraph of the Articles of the Association which deals with the definition of "members" of the College (No. 5) reads: "The subscribers hereto shall be members of the College." The subscribers are seven gentlemen, none of whom surely "possesses a certificate of proficiency in general nursing (medical and surgical)." The next paragraph of the Articles (No. 6) defines certain further qualifications for membership of the College other than being upon the Register.

If the secretary of the College of Nursing, Limited, can refer precisely to any paragraphs in the Memorandum or Articles which support the statements made in the letter to THE LANCET she will be doing a service to the College.

I am, Sir, yours faithfully,

Dec. 19th, 1916. ONE OF YOUR IRISH CORRESPONDENTS.

R. H. W.—An official communication on Trinitrotoluene Poisoning appeared in THE LANCET of Dec. 16th, 1916, and was the subject of a leading article in the same issue. The Physiological Effects of Nitroglycerine are dealt with briefly by Hale White ("Materia Medica," fifteenth edition, Churchill, 1916, p. 317), and Bruce and Dilling ("Materia Medica," tenth edition, Cassell, 1915, p. 299); and at greater length by Cushny ("Pharmacology," sixth edition, Churchill, 1915, p. 387).

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

## Medical Diary for the ensuing Week.

#### SOCIETIES.

SOCIETY FOR THE STUDY OF INEBRIETY, Rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W.  
TUESDAY.—3.30 P.M., Council Meeting, 4 P.M., Discussion on Alcoholism and Child Welfare in War Time (opened by Sir John Kirk, J.P.).

HUNTERIAN SOCIETY, at the Royal Society of Medicine, 1, Wimpole-street, W.

WEDNESDAY.—8.30 P.M., Council Meeting, 9 P.M., Hunterian Lecture.—Mr. J. W. T. Walker: The Bladder in Gunshot and other Injuries of the Spinal Cord.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.  
FRIDAY.—8 P.M., Special Clinical Evening.

#### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

- FRIDAY.**—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
- SATURDAY.**—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.
- NORTH-EAST LONDON POST-GRADUATE COLLEGE,** Prince of Wales's General Hospital, Tottenham, N.
- MONDAY.**—Clinics:—10.30 A.M., Surgical Out-patients (Mr. H. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham); Gynaecological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).
- TUESDAY**—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).
- WEDNESDAY.**—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).
- THURSDAY.**—2.30 P.M., Gynaecological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).
- FRIDAY.**—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. H. Gillespie); Eye Out-patients (Mr. R. P. Brooks).
- THE THROAT HOSPITAL,** Golden-square, W.
- MONDAY.**—5.15 P.M., Special Demonstration of Selected Cases.
- TUESDAY.**—5.15 P.M., Clinical Lecture.
- ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN,** 49, Leicester-square, W.C.
- TUESDAY.**—4 P.M., Dr. J. L. Bunch: The Treatment of Syphilis. 6 P.M., Dr. W. K. Sibley: Syphilis and its Treatment.
- THURSDAY.**—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: The Early Lesions of Syphilis and their Treatment.
- ROYAL INSTITUTION OF GREAT BRITAIN,** Albemarle-street, Piccadilly, W.
- Christmas Lectures:—The Human Machine which All must Work (adapted to a Juvenile Audience).
- TUESDAY.**—Prof. A. Keith: Living Wires and Central Exchanges.

### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To the EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if

THE  
Horace Dobell Lecture  
ON THE

MECHANISM OF THE SERUM REACTIONS

*Delivered before the Royal College of Physicians of London on Nov. 7th, 1916,*

By H. R. DEAN, M.D. OXON., F.R.C.P. LOND.,  
PROFESSOR OF PATHOLOGY, UNIVERSITY OF MANCHESTER.

MR. PRESIDENT AND GENTLEMEN.—The serum reactions are those which take place between an antigen and its homologous antiserum. Of the chemical nature of antigens we have no certain knowledge. Examples are bacteria and their products, red cells and blood serum when injected into an animal of different species. Substances capable of acting as antigens appear to be attached to protein matter and have not as yet been isolated in a pure state. Attempts have been made to show that antigens are of a lipid nature. Antigen-containing substances have been extracted with alcohol and ether, and the material obtained after evaporation of the solvent has been injected into animals (Bang and Forssman, 1906, and others). The results obtained have not been conclusive (Ritchie and Miller, 1913). In this connexion it must be remembered that antigens are active in very small amounts, and that an ethereal solution of lipoids, although apparently perfectly clear, may well contain minute fragments of protein matter in suspension. Moreover, substances not usually soluble in fat solvents may be dissolved or taken up as a very fine suspension in the presence of lecithin. A chloroform solution of lecithin is able to take up or dissolve such substances as cobra venom, trypsin, rennet, and even oxide of iron. In no case, so far as I am aware, has the injection of a pure substance of well-defined chemical constitution been followed by the formation of antibodies. Our definition of antigen is a substance the introduction of which into the animal body is followed by the formation of a specific antibody.

It is usually held (Pick, 1902) that the antibodies are for the greater part precipitated with the globulins of the serum, with the pseudoglobulin fraction in the case of the horse, with the euglobulin fraction in the case of the goat. Moreover, an increase in the globulins of the serum during the process of immunisation has, on several occasions, been observed. It is, however, probable that euglobulin and pseudoglobulin merely represent different phases of physical aggregation of their constituent particles, and the difference between even albumin and globulin may be of a physical rather than chemical nature. From this point of view, the fact that the greater part of the antibody in a serum is precipitated with any particular fraction of globulin yields no information as to the chemical nature of the actual antibody. As a matter of fact, it was shown by Ledingham (1907) that the ratio of distribution of antitoxin among the various serum proteins—euglobulin, pseudoglobulin, and albumin—differed considerably at different stages of the process of immunisation. We may suppose that the process of immunisation is accompanied by a disturbance of the physical state of the serum proteins, and the regrouping of protein molecules may lead to an increase in the globulin fraction.

As to the chemical nature of antigen and antibody we are in complete ignorance. When, however, antigen is mixed with antibody a reaction takes place, and the occurrence of this reaction can be shown by certain phenomena known as the serum reactions. These reactions are: 1. *The precipitation reaction.* When a normal serum or a bacterial extract is mixed with its homologous antiserum a precipitate is formed. 2. *The agglutination reaction.* When a suspension of red blood corpuscles or bacteria is mixed with homologous antiserum the bacteria or cells are agglutinated to form clumps. 3. *Lysis.* When red corpuscles or bacteria are mixed with antiserum or complement the cells are dissolved, or at any rate some change takes place which leads to the escape of the intracellular contents. 4. *Complement fixation.* When antigen is mixed with antiserum and complement, the complement is used up, and if subsequently there be added a mixture of red blood corpuscles and homologous antiserum the fixation of the complement can be demon-

strated by the absence of haemolysis. 5. *The opsonic reaction.* If red cells or bacteria are treated with antiserum the cells or bacteria are so altered that they are more readily ingested by phagocytes. This reaction is more marked in the presence of complement.

THEORIES IN EXPLANATION OF THE SERUM REACTIONS.

Two main theories have been advanced to explain these reactions: the theory of Ehrlich and the theory of Bordet. The former theory assumes a chemical union between the antigen and the antibody; the other interprets the reactions as adsorption phenomena in which the antibody is adsorbed by the antigen. In spite of some opposition, the theory of Ehrlich has acquired a dominant position in medical literature, and its general outline is familiar to all who have even the scantiest knowledge of medical sciences.

According to the views of the Ehrlich school each of the serum reactions is due to the existence of a separate and particular antibody. These various and hypothetical antibodies have been arranged in three classes. *Receptors of the first order:* To this class belong the antitoxins, which possess a haptophore group, a grouping of atoms capable of satisfying the affinities of the corresponding grouping in the haptophore molecule of the homologous toxin. The toxin molecule is thus rendered harmless, for it is no longer able to combine with the cells of the body. *Receptors of the second order:* These have, in addition to the haptophore group, a second group, the ergophore group, which by virtue of its chemical constitution is able to bring about the change peculiar to the particular type of antibody. To this class belong the precipitins and agglutinins. The haptophore group of the agglutinin combines with the bacterium, and subsequently the ergophore group proceeds to produce agglutination. *Receptors of the third order:* In addition to the haptophore group the antibodies possess a complementophile group, which combines with a substance called complement which is necessary to complete the lysis of a corpuscle or bacterium. The antibodies concerned in the complement-fixation reaction are held by many to constitute a separate class of amboceptor, and the opsonins or bacteriotropins are also considered to belong to this group.

It is assumed, then, that each serum reaction is an entirely separate and distinct phenomenon, the result of the action of a highly specialised chemical substance expressly manufactured for the purpose. A precipitin is a body which combines with homologous antigen, and then by virtue of a special chemical formula proceeds to precipitate it. It is entirely distinct from the complement-binding amboceptor, which is structurally adapted to perform the specific function of complement fixation. It is manifest that the side-chain theory affords no explanation whatever of the mechanism of the serum reactions. It may, as a matter of mere terminology, be convenient to say that any serum contains an agglutinin for *B. typhosus*, but the process of agglutination is in no way explained by saying that the agglutinin possesses two groups, the one a haptophore which combines with the bacillus, the other an ergophore which produces agglutination. We already know that clumping occurs and that the reaction is specific. Ignorance, however aptly veiled in an attractive terminology, remains ignorance.

With each addition to the store of experimental fact new substances have been imagined and endowed with the appropriate functions. To difficulties in the interpretation of the reaction between toxin and antitoxin we owe the coining of such words as prototoxin, syntoxoid, and epitoxoid. The observation that bacteriolysis does not occur in the presence of a great relative excess of antiserum led Neisser and Wechsberg (1901) to elaborate the hypothetical conception of complement deviation<sup>1</sup> (*Komplement-Ablenkung*). The experimental facts are explained in this case by supposing that free amboceptors have a greater affinity for complement than those which have effected union with the receptors of the bacillus. Ferrata (1907) showed by precipitating the euglobulin of fresh serum that two substances appeared to be necessary for complement action. The names mid-piece and end-piece fraction of the complement were accordingly coined, and the diagrams which accompany Brand's article (1907) are examples of the attempt to make new experimental data conform to the limits of a ruling hypothesis.

<sup>1</sup> Complement deviation (*Ablenkung*) should not be confused with the more familiar complement fixation (*Bindung*).

A theory, right or wrong, is of value as long as it tends to progress and further investigation, and it is notorious that the researches of Ehrlich and his school have yielded results of high theoretical interest and great practical value, in the realms alike of diagnosis and therapeutics. Nevertheless, the outstanding genius of Ehrlich and the greatness of his discoveries have tended to give to the theory associated with his name a position comparable to that of a well-known law of physical or biological science. New observations have been held to be explained if they were shown to be consistent with the side-chain hypothesis. But agglutinins, precipitins, amoebocytes are mere words, and a passive belief in the existence of such bodies tends to impede rather than advance our understanding of what is actually taking place. In our present state of ignorance of the nature of the reaction it seems undesirable to use a terminology which implies a knowledge which we do not possess.

We know that when substances containing antigens are mixed with substances containing antibodies a change takes place, and we can obtain indirect evidence of this change by observing certain phenomena such as precipitation, agglutination, or lysis. It seems to me probable that these phenomena are the result of one fundamental reaction which takes place between antigen and antibody. The so-called serum reactions, precipitation, agglutination, lysis, complement fixation, and the opsonic reaction constitute different methods for the indirect observation of one reaction which underlies and is essential to them all.<sup>2</sup> They are, in fact, accessory phenomena, and their demonstration is dependent on accessory characteristics in the reagents which we employ. For all the reactions which can be demonstrated in a test-tube it is only necessary to postulate one kind of antibody.

#### PRECIPITATION.

This is a reaction which is usually demonstrated by mixing antiserum with an antigen-containing fluid. According to the side-chain hypothesis the antiserum contains an active substance, the precipitin which precipitates the antigen, called in this reaction the precipitinogen. That any person who had carried out many precipitation reactions should continue to hold this view is not a little surprising. In practice relatively large amounts of antiserum are invariably employed, while the antigen-containing serum may be employed in quantities of 0.0001 c.c., 0.00001 c.c., or in exceptional cases still smaller amounts. That a fairly abundant and easily visible precipitate could be derived from such a minute quantity of antigen is scarcely conceivable. It is to Welsh and Chapman (1906 to 1910) that we owe a most important observation on this subject. These workers showed by gravimetric methods that, under the usual experimental conditions, the greater part, if not all of the precipitate was derived from the antiserum. Table I., abbreviated from a paper in the Proceedings of the Royal Society (1907) by Welsh and Chapman, illustrates this point.

TABLE I.

No. of experiment.	Weight of egg-white homologous protein (dried).	Amount of antiserum (fresh).	Weight of precipitum (dried).
1	2.5 mg.	19 c.c.	18.0 mg.
2	2.5 mg.	20 c.c.	18.0 mg.
5 (a)	1.0 mg.	18 c.c.	13.0 mg.
5 (b)	Superfluid of 5 (a).	16 c.c.	8.5 mg.
5 (c)	" " 5 (b).	18 c.c.	4.4 mg.

In experiment (1) 2.5 mg. dried hen egg-white interacted once with 19 c.c. fresh hen egg antiserum and caused the formation of a deposit weighing 18 mg., or more than seven times the weight of the homologous protein concerned. In experiment (5) 1 mg. of dried hen egg-white, interacting (a) with 18 c.c. fresh hen egg antiserum, brought down a deposit of 13 mg. The residual protein in the clear superfluid, interacting (b) with 16 c.c. of a second fresh hen egg antiserum, gave a further deposit of 8.5 mg. The resulting superfluid, again interacting (c) with 18 c.c. of a third egg antiserum, gave a third deposit of 4.4 mg. Thus by allowing 1 mg. of the homologous protein to interact successively with three antisera (which did not mutually interact), a total deposit of 25.9 mg. was obtained.

<sup>2</sup> The reaction which takes place between toxin and antitoxin is not accompanied by any change which can be demonstrated *in vitro* and appears to be of a somewhat different nature to that which takes place in the serum reactions, which are here considered.

On the other hand, the weight of the precipitate is directly proportional to the amount of antiserum, provided that the mixture contains sufficient antigen to precipitate all the precipitable matter in the antiserum. This second point is illustrated in Table II., taken from Chapman's paper in the Proceedings of the Royal Society (1910).

TABLE II.

Weight of dried egg-white.	Volume of antiserum.	Weight of precipitate.	Weight of precipitate from 1 c.c. antiserum.
14.4 mg.	2 c.c.	3.2 mg.	1.6 mg.
36.0 mg.	2 c.c.	3.5 mg.	1.75 mg.
144.0 mg.	2 c.c.	3.4 mg.	1.7 mg.
432.0 mg.	2 c.c.	3.4 mg.	1.7 mg.

If, however, the mixture contains an insufficient quantity of antigen precipitation is incomplete and a smaller precipitate is obtained. The proof given by Welsh and Chapman that under the usual experimental conditions it is the antiserum which is precipitated by the antigen is of far-reaching importance. It casts an entirely fresh light not merely on the precipitation reaction, but on the other serum reactions as well.

Before leaving the subject of precipitation it is necessary to refer to the importance of the relative proportions of antigen and antiserum in the mixture. The importance of this factor is shown in Table III. (Dean, 1911):—

TABLE III.

	5 c.c. dilutions of normal horse serum (antigen).	5 c.c. of a 1 in 5 dilution of rabbit v. horse serum (antibody).	5 c.c. of a 1 in 10 dilution of rabbit v. horse serum.	5 c.c. normal saline solution.
1	Undiluted serum.	70 c.m.m.	5 c.m.m.	Clear.
2	Diluted 1 in 2	140 "	30 "	"
3	1 in 4	190 "	65 "	"
4	1 in 8	200 "	80 "	"
5	1 in 16	110 "	120 "	"
6	1 in 32	69 "	60 "	"
7	1 in 64	40 "	25 "	"
8	1 in 128	30 "	15 "	"
9	1 in 256	20 "	7.5 "	"
10	1 in 512	10 "	5 "	"
11	1 in 1024	7.5 "	Less than 5 "	"
12	5 c.c. normal saline solution.	Clear.	Clear.	—

Three sets of dilutions of horse serum were prepared. To one set was added an equal quantity of a 1 in 5 dilution of antiserum, to another set was added a 1 in 10 dilution of the antiserum. The third set received an equal quantity of normal saline solution, and acted as an antigen control. The antiserum controls are shown in the tubes numbered 12. All the tubes were incubated for four hours at 37°C., and then placed overnight in the cold room. The tubes were then centrifuged for one hour. The tubes ended in a narrow portion, which was calibrated in such a way that the amount of the precipitate could be accurately determined. The relative quantities of the precipitate in each tube are indicated by the figures, which give the volume of the precipitate in cubic millimetres.

With a 1 in 5 dilution of antiserum the largest precipitate was obtained by adding a 1 in 8 dilution of antigen. With half the quantity of antiserum (1 in 10) the largest precipitate was obtained by adding a 1 in 16 dilution of antigen. The largest precipitate obtained with the 1 in 10 dilution of antiserum was about half the largest amount obtained by the use of twice as much antiserum (1 in 5 dilution). For any quantity of antiserum there exists a quantity of antigen which is capable within a definite period of time of producing the largest precipitate obtainable from such a quantity of antiserum. Table III. also illustrates very clearly the inhibitory effect of relative excess of antigen. This is plainly seen by comparing the figures in the two columns. A 1 in 4 antigen dilution, which constituted a marked antigen excess for an equal quantity of 1 in 10 antiserum, produced almost the largest precipitate of the series when mixed with a 1 in 5 dilution of antiserum.

The relative proportions of antigen and antibody constitute a factor which is present in all the serum reactions. This influence of relative proportions suggests an analogy with the precipitate which is formed when an electro-positive is mixed with an electro-negative colloid. In this case, if the proportions are optimal, both colloids are completely precipitated. If either constituent is present in relative excess precipitation is incomplete. Moreschi (1906) concluded as

the result of a series of experiments that precipitin and precipitinogen unite in variable proportion to form a series of precipitates. This result is at variance with the conclusions of Welsh and Chapman. The matter is one which merits further investigation.

If, then, antigen is mixed with antibody there follows an aggregation of particles, with the formation in all probability of an adsorption compound. This aggregation is an essential part of the mechanism of all the serum reactions, not merely of the precipitin reaction, but also of agglutination, lysis, complement fixation, and in all probability the opsonic reaction. If sufficient antiserum is used, and if the proportions of antigen and antibody are correctly adjusted, there is formed a bulky and flocculent precipitate. If the mixture contains a relative excess of either antigen or antibody the aggregation process is less complete. Here it may be mentioned that the ordinary method of performing the test in which a few cubic centimetres of the mixture are placed in an ordinary test-tube is not an ideal method of observing a finely-divided precipitate. A mixture of antigen and anti-serum which looks as clear as water in an ordinary test-tube may appear opalescent or even turbid if viewed through the length of a polarimeter tube.

#### THE RELATION BETWEEN THE FORMATION OF A PRECIPITATE AND THE FIXATION OF COMPLEMENT.

Complement fixation, which since the introduction of the Wassermann reaction has become comparatively familiar, was first observed by Bordet and Gengou in 1901. Interest in the subject was revived by Neisser and Sachs (1905), who elaborated a practical method for the identification of the blood of different kinds of animals. As to the explanation of the phenomenon considerable controversy has taken place. Gay (1905) came to the conclusion that the formation of a precipitate was the essential cause of the disappearance of complement. Neisser and Sachs, on the other hand, found that the amount of the precipitate and the amount of complement fixed stood in no direct proportions. They were able to observe marked fixation of complement in mixtures in which no precipitate could be recognised. They considered that the complement united with the complementophile group of an amboceptor, in strict accordance with the theories of Ehrlich. The view was accordingly propounded that precipitation and complement fixation were separate and independent phenomena. Muir and Martin (1906) found that the fixation of complement was, as a rule, closely associated with the formation of a precipitate, but were not convinced that precipitation formed a complete explanation of complement fixation. They cited as an instance a rabbit *v.* guinea-pig serum which produced, when mixed with its homologous antigen, a faint cloudiness but no definite precipitate. The capacity for fixing complement, however, was possessed by this serum to a very high degree. In other experiments they found that, if the antigen was greatly diluted, no precipitate was formed, but nevertheless the mixture was able to bind complement efficiently.

The case for the separate identity of precipitins and complement-binding antibodies rests on the following evidence. 1. Certain mixtures of antigen and antiserum in which a definite precipitate formed were shown to have little or no power to fix complement. 2. Mixtures containing very small quantities of either antigen or antiserum may appear perfectly clear and yet be shown to be very efficient for complement fixation. 3. Certain antisera give excellent results in complement-fixation experiments but yield very small precipitates. 4. If, during the process of immunisation, daily samples of serum are examined, complement fixation can as a rule be demonstrated at an earlier stage than precipitation. 5. If either the antiserum or the normal serum (antigen) be heated, the capacity for forming a precipitate may be lost, while the capacity for fixing complement may be retained. Bacterial extract kept for a time loses its power of forming a precipitate with homologous antiserum, but is still useful for the complement-fixation test. But, as will be seen from the following experiments, these difficulties can be explained without postulating the existence of two different kinds of antibody.

If a series of mixtures are prepared by adding various quantities of antigen to a constant quantity of a good antiserum, it is possible to compare the amount and state of division of the precipitate with the amount of complement fixed (Dean, 1911).

Column A represents the results of the precipitation experiment. The tubes 1 to 11 in column A contained a bulk of 10 c.c., made up of 5 c.c. of the diluted goat serum (antigen) and 5 c.c. of a 1 in 10 dilution of rabbit *v.* goat serum (antibody). The lower portion of each of these tubes was narrow and calibrated. The tubes were incubated for 4 hours at 37° C., and the progress of the precipitation was observed and recorded at regular intervals. Immediately after mixing turbidity appeared in tubes 2 and 3. At the expiration of 10 minutes flocculi were apparent in tubes 2 and 3 and tubes 1, 4, and 5 showed uniform turbidity. After half an hour large flocculi which had formed in tubes 2, 3, and 4, had fallen to the bottom of the tubes and left a clear supernatant fluid. Flocculi had formed in tube 1, but had separated less completely. Small particles were visible in tube 5 and just visible in tube 6. In tubes 7 and 8 turbidity was present without visible particles. After one hour the first 6 tubes showed a deposit and a clear supernatant fluid. Tube 7 showed small particles suspended uniformly throughout its contents. In tubes 8, 9, and 10 a progressively diminishing opalescence was seen. After four hours all the tubes were centrifugalised and the actual amount of the deposited precipitate was read. The figures are recorded in column A.

The columns B, C, and D record the results obtained in a parallel complement-fixation experiment. To obtain a quantitative estimate of the amount of complement fixed 3 doses of guinea-pig serum were employed for each of the 11 mixtures of antigen and antibody.

It is evident from a consideration of Table IV. that the proportions of antigen and antibody which produce the largest quantity of precipitate are not those which effect the greatest fixation of complement. Similar results were obtained by mixing a variety of antigens with the homologous antisera. When antigen and antibody are mixed in the proportions most favourable to precipitation the aggregation process takes place energetically and large flocculi are rapidly separated. But if the mixture contains a relatively smaller amount of antigen, precipitation is slower and less complete. These are the conditions favourable to

TABLE V.

	Precipitation Experiment.			Complement-Fixation Experiment.				Extract controls + 0.5 c.c. saline solution, 0.5 c.c. complement, 1 in 10.

**Precipitation.**—Result after 24 hours. The middle column shows the precipitation produced by mixing various quantities of typhoid extract with a constant quantity of anti-typhoid serum. The left-hand column shows the result obtained when fresh guinea-pig serum is added to these various mixtures of extract and serum. The third column shows that no precipitate is produced when normal guinea-pig serum is mixed with typhoid extract. Tube 8 in the left-hand column shows that no precipitate is produced by the mixture of the antityphoid serum with normal guinea-pig serum.

complement fixation. Under these conditions the individual particles which form the precipitate are extremely small, but present in the aggregate an enormously larger surface area than the flocculi of a coarser precipitate. It seems probable that there is a direct relationship between the surface area of the particles of the precipitate and the amount of complement fixed.

By taking any one antigen and any one antiserum and by varying the relative proportions of these two ingredients it is possible to prepare mixtures which demonstrate either precipitation without complement fixation or complement fixation without visible precipitation. The amount of complement fixed is conditioned by two factors: (1) The amount of precipitate formed and (2) the rate of precipitate formation. Complement is fixed during the very earliest stages of the aggregation process which forms the precipitate. Indeed, after the process has advanced to a visible turbidity very little complement is taken up. The relative proportions of antigen and antibody which favour rapid and complete precipitation are positively unfavourable to complement fixation. If a constant amount of antiserum be taken it will be found, as a rule, that the quantity of antigen which will produce the best complement fixation is many times less than the amount necessary to produce the largest precipitate. The reason why the two reactions do not run a parallel course is not that they are caused by two different sets of antibodies, precipitins and amboceptors, but because they represent two phases or two stages of the same reaction, and it may not be possible to demonstrate both stages under the same conditions. A flocculent precipitate represents the complete and final stage of a change which can be recognised in its earliest and incomplete stage by means of the complement-fixation method. On the other hand, if the mixture contains a very small amount of the antigen the aggregation process is extremely slow and may never proceed to the point at which even opalescence is produced. Such a condition is, however, very favourable to complement fixation.

The conditions which we have considered are those in which a relatively small amount of antigen is allowed to interact with a relatively large amount of antiserum. In these cases, although no visible precipitate is formed, the early stages of aggregation afford exactly the physical conditions which favour complement fixation. We must now consider the conditions which obtain in mixtures containing very small amounts of antiserum, and in complement-fixation tests a good antiserum can always be used in a dilution of 1 in 100, often 1 in 500, or even 1 in 1000. If, however, a cubic centimetre of a 1 in 500 dilution of antiserum be mixed with an equal quantity of a suitable

**Complement Fixation.**—This experiment shows the amount of complement fixed by mixtures of typhoid extract and antiserum identical with those used in the precipitation experiments. The dilutions of extracts, antiserum and fresh guinea-pig serum (complement) were all used in a bulk of 0.5 c.c. After one hour's incubation each tube received 0.5 c.c. of a 1 in 20 suspension of sheep corpuscles and 0.5 c.c. of a 1 in 300 dilution of haemolytic serum (rabbit v. sheep). The results were read after a second period of incubation lasting two hours.

dilution of the homologous antigen, not even a trace of a precipitate can as a rule be detected, for such a mixture contains far too little of the precipitable protein of the antiserum. What is the mechanism of complement fixation under these conditions? In a series of experiments (Dean, 1912) it was shown that if, to a mixture of antigen and antiserum which fixes complement, but produces little or no precipitate, there be added fresh guinea-pig serum, a very definite and flocculent precipitate is produced, although a comparatively long time (up to 24 hours) may elapse before precipitation is complete. An example of such an experiment is given in Table V.

Table VI.

In this experiment tubes were used, the lower portions of which were narrow and calibrated in order that the amount of precipitate formed could be measured. Only one quantity of antigen was employed (3 c.c. of a 1 in 20 dilution of typhoid extract) and one quantity of the antiserum (3 c.c. of a 1 in 20 dilution of antityphoid serum). The amount of precipitate formed by the simple mixture of the antigen and antibody is shown in the second column, Tube 8. The actual bulk of the precipitate was 10 c.mm.

\* c.d. = Centrifugalised deposit. † s.s. = Saline solution.

All the tubes were incubated for 6 hours at 37°C. The tubes were then placed in a cool room at 8°C. After 24 hours the tubes in the first column were centrifugalised and the deposits observed. All the control tubes remained absolutely clear.

The table shows that the addition of guinea-pig serum to this mixture caused a very marked increase in the bulk of the precipitate. In the tubes containing the large quantities of guinea-pig serum the bulk of the precipitate was twice and three times as great as the precipitate produced in the simple mixture of antigen and antibody. It is difficult to escape the conclusion that the larger precipitates were partly derived from the proteids of the guinea-pig serum.

Similar results were obtained in a large series of experiments in which various antigen-antibody systems were employed. Normal horse and normal sheep serum were shown to be as effective as guinea-pig serum in adding to the bulk of the precipitate. Similar results were obtained if in place of the whole guinea-pig serum a solution of guinea-pig euglobulin was employed. These experiments led to the conclusion that the interaction of antigen and antibody may cause the precipitation of the globulin of a normal serum if such is added to the mixture. That this precipitation of the globulin of normal guinea-pig serum is an essential part of the mechanism of complement fixation can hardly be doubted. It will be remembered that if euglobulin is precipitated from fresh guinea-pig serum by distilled water or weak acid, the complement is split in two fractions, the so-called mid-piece and the end-piece. The mid-piece fraction is carried down with the precipitated euglobulin while the end-piece remains in solution (Ferrata, 1907; Brand, 1907; Liefmann, 1909; Sachs and Altmann, 1909). Moreover, in complement-fixation experiments the mid-piece is bound to a much greater extent than the end-piece (Swirsky, 1910; Henderson Smith, 1910; Sachs and Bolkowska, 1910; Amako, 1910; and Gengou, 1911). It may, however, well be doubted if any such substance as the mid-piece fraction of the complement exists. The action of the so-called mid-piece may be entirely due to the physical state of the adsorbed particles of euglobulin.

It has already been mentioned that these precipitates, which occurred in mixtures of antigen, antibody, and complement, were often not formed until several hours had elapsed. The tubes were consequently often left overnight in the ice chest. This practice led to the observation that these precipitates are formed most readily at a low temperature and that, if after the precipitate has formed, the tubes are placed in an incubator at 37° C. the precipitate dissolves and the mixture becomes once more absolutely clear. On replacing the tubes in the ice chest the precipitate re-forms. The behaviour of this precipitate which forms at 0° C. and dissolves at 37° C. strengthens the belief that we are dealing with an adsorption process. At the lower temperature the adsorption of euglobulin by the minute particles of the precipitate is more complete. When the antigen is a cell or bacterium susceptible to lysis the result of this aggregation of the particles of euglobulin is the concentration of the lytic agent present in the complement (so-called end-piece) at the surface of the cell which is to be dissolved. For the subsequent and distinct reaction which causes the solution of the cell envelope a relatively high temperature (37° C.) is necessary or, at any rate, desirable. If the fixation of complement is dependent on an adsorption process we should expect that the reaction would take place with greater facility at a low rather than a high temperature.

In the experiment reproduced in Table VII, duplicate sets of the bacterial extract, the antiserum, and the complement

were prepared. Set A was warmed to 37° C. and Set B was cooled to 0° C. Antigen, antibody, and complement were then mixed in the proportions indicated in the table. Set A was then kept for half an hour at 37° C. and Set B for half an hour at 0° C. Both sets were then exposed to room temperature for one hour. Blood and haemolytic serum were then added to each tube and all tubes were then incubated for two hours at 37° C. The results show a very marked difference between the two sets.

This experiment shows that in a mixture of typhoid extract and antityphoid serum far more complement is fixed at 0° C. than at 37° C. Similar results have been obtained with serum and homologous antiserum and with the Wassermann reaction.

Moreover, if an experiment be devised to show the rate at which the reaction occurs at the two temperatures it is possible to demonstrate that, although the reaction takes place more rapidly at 37° C., the actual amount of complement fixed is much greater at 0° C. This result is best explained on the assumption that complement fixation is a process of adsorption.

#### AGGLUTINATION.

The explanation of the agglutination reaction as an adsorption phenomenon has been the thesis of many contributions to the literature of immunity. Bordet (1899) considered that agglutinin is adsorbed by the bacilli as dye is adsorbed by filter paper. The aggregation of the bacilli is then brought about by changes in the molecular attraction between the bacilli and the surrounding medium. The question of agglutination was very thoroughly studied from the adsorption standpoint by Craw (1905). Craw showed that the rate of addition of bacillary suspensions to agglutinating serum is a factor determining the amount of agglutinin fixed by the bacilli. By adding a suspension of bacteria in parts to the antiserum Craw was able to show that more agglutinin was removed than is the case when the whole amount of bacillary suspension is added at once.

The process of agglutination is probably brought about by an interaction between the antiserum and antigen which has passed out from the bacillus into the medium which immediately surrounds it. The result of this interaction is the aggregation of the particles of the globulin of the antiserum on the surface of the bacillus. In other words, the proteins of the antiserum are adsorbed by the bacillus. For the production of agglutination the presence of precipitable protein is essential. If to a mixture of bacillary emulsion and diluted antiserum there be added a third ingredient, normal serum, the agglutination of the bacteria is rendered more complete. This reinforcement of the proteins of the antiserum by those of a normal serum has been called conglutination. This phenomenon was described independently in 1906 by Muir and Browning and by Bordet and Gay.

The substance present in normal serum which is able to aid the agglutination of red cells or bacteria by the homologous antiserum appears to be the euglobulin (Dean, 1911). The effect of adding various dilutions of euglobulin solution to mixtures containing sheep cells and various quantities of the homologous antiserum is seen in Table VIII.

TABLE VIII.

1 c.c. of dilution of haemolytic serum, rabbit v. sheep.	+ 1 c.c. middle-piece solution diluted.				+ 1 c.c. normal saline.
	1-10	1-20	1-40	1-80	
1	+++	++++	++++	++++	+++
2	+++	++++	++++	++++	+++
3	+++	++++	++++	++++	+++
4	+++	++++	++++	+++	++
5	+++	+++	+++	+	+
6	+++	+++	+	0	0
7	+++	+	0	0	0
8	+++	+	0	0	0
9	1 c.c. normal saline.	0	0	0	0

Each tube contained a volume of 3 c.c. made up of 1 c.c. of a 1 in 20 suspension of washed red cells of the sheep, 1 c.c. of a dilution of heated haemolytic serum (rabbit v. sheep), and 1 c.c. of the diluted middle-piece solution. The tubes numbered 9, in each row, contained no immune serum and the bulk was made up to 3 c.c. by the addition of 1 c.c. of normal saline solution. In these tubes no agglutination occurred, the middle-piece solution by itself being unable to agglutinate the red cells. The tubes in the last column contained 1 c.c. of the suspension of red cells, 1 c.c. of a

d lution of the haemolytic serum, and 1 c.c. of normal saline solution. The agglutinative power of the immune body acting by itself is shown in this column. In the remaining columns is shown the effect of the combined action of the immune body and the middle-piece solution.

That in such a reaction the euglobulin is actually precipitated may be shown by an experiment similar to that shown in Table IX.

TABLE IX.

Tube	Solution of laked corpuscles	Antiserum, rabbit v. sheep cells, 1 in 200.	Normal saline solution.	Solution of middle-piece 1 in 10.	Normal saline solution.
1	c.c.	c.c.	c.c.	c.c.	c.c.
2	5	5	—	10	—
3	5	5	5	10	—
4	—	5	5	10	10

One cubic centimetre of thoroughly washed sheep corpuscles was laked with 9 c.c. of distilled water. The solution of corpuscles was made up to the usual saline content by the addition of 10 c.c. of 1·7 per cent. sodium chloride solution. After filtering many times through filter paper a perfectly clear solution was obtained, representing a 1 in 20 solution of red corpuscles in normal saline. The following mixtures were then prepared:

In tube 1, 5 c.c. of the solution of corpuscles was added to 5 c.c. of the diluted antiserum. In the control tubes 2, 3, and 4 the ingredients indicated in the first three columns were mixed. The volume in each tube was then 10 c.c. All the tubes were allowed to remain for one hour at room temperature. They were then examined, and the contents were found to be absolutely clear. To tubes 1, 2, and 4 were then added 10 c.c. of the 1 in 10 middle-piece solution; to tube 3 was added 10 c.c. of normal saline solution. All four tubes were then incubated for four hours at 37° C. and then placed for 12 hours in a cool chamber at about 8° C. Tube 1 was then found to contain a small but definite white flocculent deposit. The three control tubes remained absolutely clear.

#### CONCLUSIONS.

In discussing the merits of rival theories of the mechanism of the serum reactions it has been frequently observed that Ehrlich's hypothesis alone provides an explanation of the problem of specificity. The value of the side-chain theory as an explanation of specificity may, however, be doubted. To say that antigen unites with antibody as a key fits a lock is no explanation at all. It is merely a diagrammatic representation of the supposed facts. Of the nature of the fundamental reaction between antigen and antibody we have, at the present time, no knowledge. But, in all the serum reactions which have been above considered, the immediate consequence is an aggregation of globulin particles around the antigen. The degree to which the aggregation or precipitation proceeds depends entirely on the experimental conditions, on the relative proportions of antigen and antibody in the mixture, on the nature of the antigen-containing substance, red corpuscle, bacillus, or normal serum, on the presence of some third factor, a normal serum containing complement or conglutinin. In other words, the various serum reactions are various methods of observing and measuring one single reaction. The simplest of these reactions is the precipitation reaction, for in it the formation of the precipitate is directly observed. In the other reactions the aggregation of particles may be less complete and the change is measured by indirect methods.

The main phenomena are most readily accounted for by Bordet's adsorption theory, and no useful purpose would seem to be served by postulating the existence of a separate kind of antibody for each of these reactions. The reactions are no doubt of a very complex nature, as all reactions which occur in a mixture of colloids must be, and it is to be anticipated that great difficulties must be encountered before any entirely satisfactory explanation is arrived at. Similar difficulties have been met with in the past, whenever the attempt has been made to explain physiological phenomena in the light of the laws of chemistry and physics. These difficulties will in time be met and with a more perfect knowledge of the mechanism of the serum reactions there will be attained a more perfect knowledge of the laws which govern both natural and acquired immunity.

## Presidential Address

ON

### THE STATE OCTOPUS AND THE MEDICAL PROFESSION.

Delivered at the Harveian Society of London on Jan. 11th, 1917,

By EDMUND CAUTLEY, M.D. CAMB.,  
F.R.C.P. LOND.,

SENIOR PHYSICIAN AT THE METROPOLITAN HOSPITAL AND THE BELGRAVE HOSPITAL FOR CHILDREN.

GENTLEMEN.—Year by year the State, like an octopus stretching out one or more of its tentacles, grasps and absorbs some portion of the rights, privileges, or emoluments of the medical profession or the public. I propose to indicate roughly, for time will not permit me to do so in great detail, the methods and progress of this absorption. I shall appreciate its value to the public, even if it is detrimental to our profession as a whole or to individual sections of it, for I hold the opinion that the public welfare is our highest aim and object. And I shall try to gauge its progress and suggest the best methods for watching and directing its course.

#### CHANGED RELATIONSHIP OF THE STATE, THE PUBLIC, AND THE MEDICAL PROFESSION.

Half a century ago there was little State interference with the medical profession, and few burdens, except registration, were laid upon it. At this remote period it was customary for the eminent lecturer who gave an opening address at a medical school to speak in grandiloquent language of the noble aims of our profession. It was generally insisted that the student must not enter on its pursuit for the sake of filthy lucre, that the good of the public was alone of importance, and that life should be lived on a basis of pure altruism, even if it did not provide substantial meals. Verily an opening address was a true eye-opener. The lecturer was usually a successful man who did not realise the needs of the common herd or had forgotten earlier impecunious days, though occasionally one was bold enough to recall the principle that the labourer is worthy of his hire, or else he spoke with his tongue in his cheek.

Even in those days the State exploited the services of the profession, for the medical attendant was compelled to give a death certificate without fee. And if he happened to be an officer of a public institution and an inquest were held on a patient who died therein, he had to give expert evidence when called on; he had to make a skilled post-mortem examination should the coroner order one; and he had to waste valuable time in the precincts of the court; and all this without fee or reward, receiving thanks rarely and ungracious criticism not infrequently. No wonder it is

more satisfactory, as this exploitation of our youngest members still exists, that the patient should die on the steps of the hospital rather than across the threshold.

Under the Public Health Act of 1875 urban and rural sanitary districts were formed. Medical officers of health were appointed in charge of these districts. A diploma in public health was evolved in order to specialise this branch of service and supply evidence of the examinational qualifications of those applying for such posts. Since then the medical officer of health, though often underpaid, has developed into a being of imposing power and authority, under the *egis* of the Local Government Board. In a sense he is the lily of the profession, for he toils not neither does he spin in the practice of medicine, unless he is in charge of an isolation hospital. He is no longer a medical man; he has sloughed his skin and unfortunately has become a departmental official, to whom the interests of the profession are only of minor importance.

Many of the burdens thrust upon our patient shoulders have arisen through the uncontrolled activities of these officers or at their instigation. Thus, we have to notify cases of infectious disease. Year by year more and more diseases are included in this category; perhaps at first only in some urban district and on the *ipse dixit* of a medical officer of health, who speaks to his local council with the dogmatic voice of a god, for he alone is assumed to have knowledge of the subject. For instance, notification of whooping-cough is insisted on in some districts in spite of the fact that there is no evidence of its value in reducing the spread of the disease, and that, generally speaking, it is not diagnosed among the poorer classes until the whoop is characteristic and the infectious stage almost over. Poliomyelitis has also been added to the list, although there is no evidence of its conveyance by direct infection. And in 1913-14 ophthalmia neonatorum was wisely added. Of course the main object of notification is to control the spread of the disease and isolate its source. It sometimes is beneficial in leading to efficient treatment. But I maintain that no disease should be made notifiable unless such a measure is approved by an authoritative body representative of our profession.

In 1907 the medical inspection of school children was authorised by Parliament and medical officers were appointed for this purpose. It was not a great step onward to the treatment of enlarged tonsils and adenoids and errors of refraction. This is partly carried out in hospitals and partly by general practitioners in semi-private clinics. Seeing that severe haemorrhage is possible after operation, such clinics ought to be provided with an emergency bed. Possibly a further step will be the treatment of all ailments in school children at these clinics and the gradual evolution of numerous small centres of semi-hospital practice, which may or may not be to the advantage of the public and the profession. Bear in mind that the school doctor does not treat these patients at present. He measures and he weighs them, collecting masses of statistics. He examines them and recommends treatment. He, too, has become a departmental officer.

The Public Health (Tuberculosis) Regulations of 1912 have transferred the treatment of tuberculous patients in great measure to public officials with medical qualifications. These patients now come under the conjoint charge of the medical officer of health, the medical officer of the tuberculosis dispensary, and perhaps a sanatorium medical officer. It is possible that all cases, rich and poor, will eventually be brought under such control and that the treatment of patients with tuberculosis, especially of the lungs, will pass out of the hands of the general practitioners into those of departmental officers.

The Mental Deficiency Act of 1913, in operation since April 1st, 1914, has also affected our relations with the public and the State.

The National Insurance Act brings home to us the profound changes which are taking place in the relationship between the medical profession and the public, through the medium of the State and its various subordinate bodies, such as county and borough councils, municipal bodies, and boards of guardians.

#### "MENTALITIES."

Let me digress for a moment and, after the style of a virulent medical controversialist, make a few preliminary remarks on what are at present called "mentalities." Let me premise that "change" is not synonymous with "progress," though to some minds all change is progress.

In actual life we meet with two distinct types of mentality, though the bulk of mankind occupy an intermediate position. One man goes baldheaded for change. He is an iconoclast. He destroys an existing institution because he sees evil in it, but he lacks the intelligence or the patience to think out logically the alternative scheme in his mind and the evils likely to develop in his new Utopia. The Insurance Act and other political measures are priceless illustrations of this character.

In golden visions a new land legislation was going to hand over that Castle in Spain, the latent wealth in our agricultural industry, to those unfortunate men, the failures in the towns. They were to go "back to the land" and earn vast sums from the cultivation of the ground in spite of their lack of training and education in one of the most difficult of trades, one which can only be learnt thoroughly by an intimate experience from childhood of all the processes of agriculture.

So, too, vast sums were to be drained into the Treasury by means of an increment duty. The result, as foretold by the opponents of this measure, has been a great pecuniary loss to the Treasury and a disadvantage to the poor, by reducing the provision of cottages and inducing a rise in rents. Rather than attempt to raise money and at the same time put a drag on the building industry, it would have been wiser and cheaper to spend five millions a year, one day's war expenditure, on the building of cottages and other dwellings for the wage-earning classes.

Usually the man of this type regards the medical profession as a "monopoly"—that blessed word which damns without explanation of its meaning. He little knows that the monopoly consists in the payment of fees to the State, for various degrees and a licence to practise, in return for an amount of protection which may be summed up in the power to sue for fees for services rendered. Neither the public nor the profession is protected against the evils of quacks and quack medicines. Anyone may practise our art in all its branches so long as he does not pretend he is a qualified medical practitioner, though he is liable to prosecution for manslaughter if his patient dies. And under the Apothecaries Act of 1815, Section xx., he is liable to a penalty (fine) if he practises as an apothecary. Of so little value is this State protection that probably any one of you would make a larger income out of our woolly-headed public by dropping your titles and diplomas and advertising a sure remedy for all the ailments of mankind. I would suggest a pill which acts mildly and efficiently, purging the vile body of all its ill humours and the afflatus which is not divine.

The other type of man is less adventurous in the doing of good or evil by interference with the ordinary routine of life. He does not set the world ablaze to advertise his own importance. He is devoid of the vanity which lies at the root of the desire to put the world to rights. He is more or less satisfied that all is for the best in the best of all possible worlds, and that it is better to endure the ills he knows than to stir up others which may be worse. Such a man becomes stereotyped in thought and action, in speech more dogmatic as his arteries harden, and somewhat intolerant of new ideas, even if of German origin. Steadily and satisfactorily he conducts the routine business of the little world in which he lives. Slowly and cautiously he tests, and perhaps adopts, new hypotheses and fresh methods of treatment. In the face of fresh ideas it is his habit to "wait and see." Yet, withal, he is tardily progressive, not wildly careering after the exploitation of some new system of treatment or synthetic drug, but patiently sifting and adding to the sum of knowledge.

Roughly, the difference between these two characteristic mentalities is like that between youth and age. Fortunately most of us occupy an intermediate position, neither wildly iconoclastic nor too rigidly stereotyped. Few seem to get beyond middle age in the realms of mind, until the final rapid subsidence into complete senility or retirement into the country and a vegetable existence. It is medical men of this intermediate type who are so badly needed on State and municipal committees. Were such an influence more in action we should not so frequently be up against some new thing, experimental in character rather than of proved value.

#### NEW SCHEMES.

I have already pointed out that many a scheme is evolved by the Local Government Board, or a subsidiary council, without obtaining the consultative opinion of any representative medical body, and often on the mere *ipse dixit* of

some local medical officer of health. Sometimes it is initiated by a self-appointed leader of the profession, who collects others like unto himself. We have had instances of this in the development of the crusade against tuberculosis. Occasionally these "leaders" are in opposition, as in the painful case of the manifesto published in favour of alcohol. But, however initiated, the scheme is set in action by an Order in Council or some local by-law, and we are expected to carry it out without murmur or protest.

As a rule these fresh burdens on the doctor are unaccompanied by fees for the extra work, or at most only nominal ones. For instance, the fee for notification of infectious disease used to be 2s. 6d. for a private and 1s. for a hospital case. It is not obvious why the extra work should be paid for at a lower rate when it is done by an underpaid doctor attached to a public institution. The profession has recently received its just reward for submitting to such an inequality in payment for identical work. Its insignificant fee of half-a-crown has been reduced to a shilling for private cases. I wonder that the shilling fee for hospital cases has not been halved. And this reduction has been enforced at a time when the doctors are doing an enormous amount of gratuitous work and the cost of living has greatly increased; and it was carried by Members of Parliament receiving £400 a year, of which £100 is free of income-tax, at a time when the services of most of them are of little value and their work in the House of Commons has much decreased.

#### THE INSURANCE ACT.

The Insurance Act is a great conception inadequately carried out. Instead of being used as a vote-catching measure, and including all employees, no matter their age and health, it should have been started on a smaller scale for the public benefit alone. It ought to have been limited at first to employees under 25 years of age, the healthiest class in the community. In the course of 40 years all the wage-earning classes up to the age of 65 years would have been insured. No doubt 40 years is too long for the politician, though but a moment in the life of a nation. I believe that the soundest policy would be to start a new scheme on these lines, independent of the present one, which would eventually lapse and be replaced by an efficient Act. In its present state the financial basis of the Act is less than doubtfully sound, its administration chaotic, its innumerable regulations almost impossible to understand, and the general result one of dissatisfaction. Practically it has resulted in a huge club system on a State basis, possessing all the evils of the old club system and none of its advantages to the members from a medical point of view, but financially profitable to the doctors and the clerical staff. As far as I can judge, the only advantage to the public is that every insured patient is entitled to demand treatment for the most trivial ailment, and a certificate enabling him to obtain sick benefit if unable to work, with the result that trivial ailments have become much more frequent and a desire of obtaining a paid holiday has led to their exaggeration.

From the public point of view I regard the medical section of the Act as a failure. It is not as good as the old club system with its admitted evils. Thousands of the insured are dissatisfied and avoid their panel doctors. Adequate treatment has not been secured—merely ordinary out-patient treatment, the patient being referred to a hospital for more serious ailments.

The Government has not carried out Mr. Lloyd George's promises. Absolute freedom as to choice of doctor is not in force; he must be on the panel. Still less is it possible to make a change when desired. Permission to make "own arrangements" outside the panel have been generally refused.

Panel doctors are practically State officials and their sympathy with the patients has diminished. There is more illness, more malingering and neurasthenia, greater prolongation of illness, and an increasing demand for certificates. Often a patient obtains a larger income when ill than when at work. Disease has to be treated more or less according to rules, and the cheaper drugs used for panel patients help to prolong illness.

Some complaints from panel patients are trivial and contemptible. The members of a society for agricultural labourers complain bitterly that the doctor now charges 5s. for examination of an applicant for membership, whereas in the old club the fee was only 2s. They refuse to pay it and

the society is languishing for want of new members. It does not appear to have been pointed out to them that the weekly wage of the labourer has gone up more than 5s., that the doctor has also to face the increased cost of living, and that in the old club the doctor took a much more sympathetic interest, regarding it as partly a charity, whereas insurance is a State affair.

And I want to lay it down as an axiom, to be borne in mind by every member of our profession, that gratuitous expert services should not be rendered to the State or any rate-levying body. No such service is appreciated at its true value. It is not charitable service to the poor, and merely lightens to an infinitesimal extent the burden on tax- and rate-payers, many of whom are much better off than the exploited doctor.

#### Payments under the Act.

Under ordinary systems of insurance it is customary to pay a premium in advance to cover a definite liability, generally for a year. The Insurance Act tempers the wind to the shorn lamb, for the insured patient has to pay weekly premiums for six months before becoming entitled to benefit. By this means a big fund was formed of contributions from the employers, employees, and the State. It should have amounted to 13s. per female and 15s. 2d. per male, apart from the State contribution. At the end of six months the work of the doctor began, and there does not seem any just reason why he should not have been paid 7s. per head at once for each patient accepted by him. Apparently the accumulated preliminary fund was devoted to payment for clerical work, a great burden on the finance of the Act—a veritable old man of the sea.

The Act fixed an annual capitation grant for medical treatment, and Mr. Lloyd George frequently stated it would be at least 7s., possibly more, as there was a lien on a floating sixpence. But agreements between the State and the profession are apparently only to be kept by the latter. In step the Insurance Commissioners, with powers above and not under the control of Parliament, and, subsequent to the signature of these agreements, regulations are issued which make the annual capitation fee a sum of no definite amount and not payable within certain limits of time. The panel doctor receives an unnamed sum, paid on uncertain dates, and "as soon as may be" after its receipt by the Commissioners.

The medical profession undertook the treatment of the insured for a minimum fee of 7s. per annum. For 1915 the payment was 5/7-96 per head. This is explained by the Commissioners as an equivalent payment, because some of the doctors' lists are inflated. It is a method for counteracting the errors due to inefficient book-keeping. It creates great injustice. A doctor with an uninflated list receives a grant deficient to the extent of 20 per cent. The Commissioners have also determined that their liability to the panel doctor ceases with the death of the patient, although the doctor undertook the contract for a year. If the insured person dies on the first day of the year the medical fund is only to get 1/365th part of 7s.; and this, in spite of the fact that the Commissioners have received payment for six months in advance. It does not appear that the State is carrying out its bargain fairly.

#### New Regulations for 1917.

Clause 3 deals with the provision of medical services by any public authority over and above those provided by panel doctors. It states, with dangerous vagueness, that under such circumstances the practitioner "shall ..... take such other steps as may be reasonably necessary in order that the patient may derive full advantage from the provision of such services." Obviously the Commissioners will decide what is "reasonable," and, as far as one can judge, they expect the doctor to provide particulars as to the past history, diagnosis, and treatment; take and send specimens for laboratory examination; and attend, if necessary, with the patient for consultation. No extra payment is suggested for this fresh burden, which may become excessive. And there is no safeguard against the extension of so-called "reasonable provisions." This regulation gives the Commissioners power to increase the duties of the panel doctors without compensation. It has been accepted at present for the treatment of venereal diseases, which are said to have increased very greatly and require more adequate methods of control. But it may be applied in many ways, if consultative advice is to be placed within the reach of panel patients,

giving the doctor much extra work and with no extra expense to the patient. Instead of reducing the annual capitation grant the tendency will be to increase the doctor's duties and obligations.

#### *The Disabled Soldier and Sailor.*

The disabled soldier and sailor have created another problem for the doctors and Commissioners. Weak-minded sentimentalists nobly say that the medical profession should shoulder the burden of looking after these heroes. But it is the State which should bear the burden, not an individual section of the community. Had the Government, with a little foresight and apparent generosity, paid into the insurance funds the full amounts due from them as employers, the full contributions of their employees, and the State grant, they might have been justified in saying that, as the medical profession had received the insurance premiums for medical services during the war, they must undertake the subsequent liability. But an extra burden has fallen on the panel doctors during the war, for a huge number of healthy lives have been removed from insurance, and the relative proportion of illness among the remainder is naturally greater. It would be grossly unfair for these men to come back into insurance with an increased sickness liability and the burden of their treatment be thrown on the panel doctors without extra payment. Special financial arrangements should be made for the treatment of the disabled when they are discharged.

#### *VENEREAL DISEASES.*

The provision of treatment for these affections under the public authorities is a great step to more efficient control, limitation of their extension, and efficacious treatment. But it is another inroad into the old relationship between the public and the profession, if it is made obligatory. So far it is not compulsory and the supporters of the scheme have not ventured to "go the whole hog." If so, notification would be essential. The main argument against it is that it would lead to concealment of disease, to evasion of treatment, or to treatment by quacks. Surely the answer is the abolition of quacks and quack medicines, and the punishment by imprisonment of anyone, except a qualified practitioner, who undertakes the treatment.

Compulsory notification has been adopted for many infectious diseases, as well as for others in which the transmission of infection by personal contact has not yet been adequately proved. Why, then, shirk it in this case? Is it because the Government fear the loss of revenue from stamp duties on patent medicines, or the attacks of newspapers which receive large sums of money for advertisements and puffs of these wares? More probably it lies in the absence of social stigma in the present notifiable diseases. On the other hand, the moral effect of notification on the rising generation would be enormous. Few young men dread infection as much as they fear being "found out" by their parents. And the risk of evasion is minimised by the provision of free treatment, for, under the new scheme, it is available for rich and poor and under safeguards as to privacy. But the whole scheme is defective, firstly, because no really authoritative medical body expressed its opinion thereon; secondly, because it establishes a new class of specialist; and thirdly, because the safeguards as to privacy are likely to prove illusory.

#### *THE OUTLOOK.*

The united efforts of panel practice, of State and municipal treatment of tuberculosis, venereal and infectious diseases, the possible provision of ante-natal and post-natal clinics, and the existence of numerous departmental medical hybrids in the shape of medical officers of health, school doctors, Poor-law and asylum doctors, tend to the establishment of a State medical service. An additional influence will be the return from the war of a large number of medical men, with no experience of civil practice, who may lack the means or the inclination to enter on such a mode of livelihood, and who may have become enamoured of an annual stipend, fixed duties, liberal freedom, and the independence of character acquired in the treatment of those submitted to their tender care and unable to change their doctor. Many will be disposed to sink to the level of the salaried official. Meetings have already been held in France, at the instigation of certain politicians, for the discussion of such a public service.

It is probable that in time each panel doctor will be limited to a definite number of panel patients—say, two to three thousand. From this it will be only a small step, and perhaps it may be advocated by the doctor, that panel practice should be limited in area and that each such doctor shall have charge of all the insured patients in a limited district. Of course, this would abolish the promised free choice of doctor, but I fancy this privilege is not often obtained or of much value. The natural sequence will be the conversion of panel practice into one of whole-time appointments. And the insurance of dependents will make this more certain, as finance on present lines will be impossible. It is obvious also that if clinics and pathological laboratories are provided for venereal diseases, a similar demand will be made for panel patients with other ailments. And, indeed, it seems logical that, if the insurance scheme is to be worked adequately on its medical side, it must be extended to the provision of hospital treatment with all the advantages pertaining thereto. Our hospitals will have to be assisted by the State or out of the rates, or taken over by the State. I am strongly opposed to the idea of a State medical service, but I see no great objection to hospitals receiving such assistance. It may necessitate a certain amount of supervision or control, possibly through the occasional visit of an inspector or by a representative on the committee of management. The amount of assistance would have to be proportionate to the work done and the facilities provided. There is no justification for hospitals putting their resources, provided as a charity by voluntary subscribers, gratuitously at the disposal of a State or rate-paid medical service.

Naturally there would be a big increase in hospital expenditure. The visiting staff of London hospitals receives no payment, or merely a nominal one, and is perfectly satisfied to give its expert aid and much time in a charitable cause. But, although it is often assumed that we will continue to give gratuitous services in return for a few gracious words of praise and an occasional title of honour, more often than not granted to some one or other of the less deserving of the profession, I think it will soon be realised that it is not charity to give such services to the State.

Recently there has been a striking illustration of the manner in which the medical profession is exploited. Although the State is responsible for the health of its officers as well as the rank and file, and reserves to its representatives the decision as to the capacity and fitness of the individual, it has accepted through the Red Cross Society and rich civilians the gratuitous services of a large number of our profession for the treatment of these officers. And I desire to remark that the treatment of officers on these lines in private houses, more or less suitable, is not, and cannot be, as good as that of the rank and file in the numerous large and well-appointed hospitals at their disposal, with the best conveniences for examination and treatment. The lack of a resident medical officer, a pathological apparatus and X ray apparatus, not to mention other defects, is a grave drawback. It is marvellous that there has been no outcry against a system so unfair to our officers.

I think it will be admitted that when valuable aids to the diagnosis and treatment of illness of all descriptions are at the disposal of the present panel patients they will be extended for the benefit of their dependents. All those receiving a weekly wage, and (or) below the income-tax limit, will be included. Do you think that the lower middle-class will be content to see the bulk of the nation provided with the best possible medical treatment, for which *they* are mulcted in high rates and taxes, without demanding similar provision, on a better scale as to environment, at a higher annual insurance fee? Treatment in a private ward in a properly equipped hospital is obviously much superior to that of any nursing home or private house. Hospitals will have to be enlarged to provide special wards for this class. The nation will be divided into the insured and the non-insured. Possibly the large group of the insured will be treated by State official doctors and the remainder will still exert the right of free choice of doctor and payment for services rendered. The State official will be a superior type of Poor-law doctor.

A State medical service will not be economical, though perhaps less extravagant than the panel system. It is suitable for those under discipline, but we do not want the nation under the heel of medical drill-sergeants. No doubt

there has been immense improvement in the control and prevention of disease by the medical department of the Local Government Board. And a certain amount of valuable work has been carried out in laboratories in reference to the cause of particular diseases. School medical officers have done good work in securing efficient treatment for hundreds of children who would otherwise have been neglected. But, so far, I have not noticed much evidence of any advance in scientific medicine, though the extension of treatment has been great and beneficial. Nor have I observed much original work done by the present State medical service—namely, the Poor-law doctors.

Further encroachment on private practice will ensue from the extension of sanatorium benefit to dependents. Wild-cat schemes have been mooted. Recently it has been suggested that, as sanatorium treatment has not produced any marked effect on the prevalence of tuberculosis, it would be better to insist on the wholesale migration of the tuberculous from unhealthy surroundings to properly supervised dwellings in pure air. It certainly would be a wholesale migration. And yet many develop tuberculosis under such conditions, while others sometimes recover though living in a most unfavourable environment.

#### SUGGESTIONS.

I hope I have made it clear that our relations with the State and the public are in a state of flux, and that it is dependent on individual members of the profession to watch and direct the course of the current. Unfortunately we have no representative body which possesses the complete confidence of our profession or the power to enforce its resolutions. The British Medical Association diminished its rapidly increasing influence by allowing some members of its council to make use of it for political purposes in connexion with the Insurance Act. At first it was remarkably successful in organising the profession in opposition to the Bill on certain lines, but some of its members broke up the concordance by holding meetings in support of the Bill. Incidentally I may remark they remained members of the Association.

Still, it is possible for the British Medical Association, if managed with greater tact, more tolerantly, and for the benefit of the profession as a whole, rather than for the advancement or advertisement of sections or individuals, to obtain and retain a valuable advisory and directing hand in the future. As our only active representative body it should receive our support, even if we do not invariably agree with its policy in particular cases.

I am strongly of the opinion that it is of the utmost importance for medical men to take a greater part in local politics and act as representatives on county councils and other local bodies. The selection of candidates for such posts should be made by the various branches of the British Medical Association, or at a joint meeting of members and non-members. But it must be borne in mind that such candidates must have no political axe to grind, and that the welfare of the public and the profession is their sole object. We do not want a repetition of the scandals in connexion with the appointments at the time the Insurance Act was in the throes of labour. Nor do we want representatives who have retired from practice through age, incompetence, or infirmity, for such posts are not those of *otium cum dignitate*. Granting efficacious leadership, it will be possible to develop a medical service, suitable to the genius of the nation, out of the present state of chaos which I have somewhat inadequately pictured. Above all, under proper leadership, it will be possible to put forward practical schemes, carefully thought out under medical guidance, rather than have to carry out the imperfectly devised experiments to which we and the public are subjected.

**THE LATE W. A. LAUDER SMITH, M.A., M.B., B.C. CANTAB.**—Dr. Lauder Smith died recently at his residence, Wells, Somerset, from pneumonia following influenza, in his fifty-second year. The deceased was highly esteemed in Wells, where he had several public appointments. The chairman of the Wells board of guardians, in alluding to the loss the board had sustained by the death of their district medical officer, said: "Dr. Smith had lived a beautiful life of self-sacrifice, and had literally worn himself out for others."

#### CASES OF CEREBRO-SPINAL FEVER IN THE ROYAL NAVY—AUGUST 1ST, 1915, TO JULY 31ST, 1916.

BY H. D. ROLLESTON, C.B., M.D.CANTAB., F.R.C.P.LOND.,  
TEMPORARY SURGEON-GENERAL, R.N.; CONSULTANT PHYSICIAN  
TO THE ROYAL NAVY, ROYAL NAVAL HOSPITAL, HASLAR;  
SENIOR PHYSICIAN, ST. GEORGE'S HOSPITAL.

##### (1) Incidence of the Cases.

DURING the year August 1st, 1915, to July 31st, 1916, there were 104 cases of cerebro-spinal fever in the Royal Navy, as compared with 170 cases during the first year of the war. This fall in the number of cases must be correlated with the contemporaneous fall in the incidence of the disease both in the civil population and also in the Army in this country.<sup>1</sup> Although the fall in the general incidence of the disease is probably the main factor in the smaller incidence in the Navy, it should be borne in mind that great care has been taken in prophylaxis, and that in the first half of 1916 bacteriological examination of swabs from the throats of new entries was made at Haslar, Chatham, Plymouth, and at Greenwich of non-contacts (new entries and drafts for sea) in order to detect "carriers." Out of 10,852 ratings examined 298, or 2·7 per cent., carriers were thus detected and isolated. Not only has the incidence been smaller, but it has been less widespread, for no case occurred at Blandford Camp or in the Akbar Establishment, in both of which there were a few cases during the first year of the war. At the Deal dépôt, which was responsible for 25 cases during the first year of the war, there were 2 cases only in the second year. No case has occurred during the war at either Osborne or Dartmouth Royal Naval Colleges.

The cases occurred in the Plymouth district (28), Portsmouth district (27), Chatham district (18), at Shotley (11), at the Crystal Palace dépôt (8), at Deal (2), and 10 cases on sea-going ships. During the first two years of the war out of 274 cases of cerebro-spinal fever in the Navy there were 22, or 8 per cent., with 13 deaths in sea-going ships. In one ship only was there more than one case (2).

The monthly incidence, with the results, is shown below. As in the first year of the war, the largest number of cases and of deaths occurred in February.

	Cases.	Deaths.	Recoveries.
1915.			
August ...	4	2 or 50·0 p.c.	2
September ...	4	3 .. 75·0 ..	1
October ...	3	1 .. 33·3 ..	2
November ...	6	5 .. 83·0 ..	1
December ...	8	4 .. 50·0 ..	4
1916.			
January ...	8	3 .. 37·5 ..	5
February ...	26	7 .. 26·9 ..	19
March ...	20	6 .. 30·0 ..	14
April ...	7	2 .. 28·5 ..	5
May ...	7	0 .. —	7
June ...	3	2 .. 66·7 ..	1
July ...	8	2 .. 25·0 ..	6
	104	37	67

**Age incidence.**—Among the 104 cases in the Navy 70, or 67·3 per cent., were under 20 years of age (83, or 79·8 per cent., being under the age of 25 years), and the number of cases progressively diminished in the succeeding decades. The percentage of deaths was lower under 20 years than in any of the succeeding decades. The average age of the 104 cases was 20·4 years, of the fatal cases 22·2, and of the recoveries 19·4 years. The extremes of age were 15 and 46 years.

Age periods.	Number of cases and percentage of the total 104 cases.	Deaths and percentage in the age periods.
15 to 19 .....	70 or 67·3 p.c.	20 or 28·5 p.c.
20 .. 29 .....	24 .. 23·1 ..	12 .. 50·0 ..
30 .. 39 .....	6 .. 5·8 ..	2 .. 34·4 ..
40 .. 49 .....	4* .. 3·8 ..	3 .. 75·0 ..
	104	37

\* The case which recovered was invalided, and died suddenly six months later, the coroner's inquest finding pneumonia as the cause of death.

<sup>1</sup> For this information I am indebted to Surgeon-Colonel R. J. Reece, B.A.C.

In the first year of the war 60·6 per cent. of the cases were under 20 years of age.

**Mortality.**—Out of the 104 cases 37, or 35·6 per cent., proved fatal; this contrasts favourably with the mortality of 90, or 52·9 per cent., among the 170 cases during the first year of the war.

**Ranks and ratings.**—There were two officers—a midshipman Royal Naval Reserve (aged 18), and a surgeon probationer (aged 21) who both recovered. The 102 ratings were as follows: Boys (seamen class) 39 (7 deaths); seamen 22 (11 deaths); stokers 13 (6 deaths); marines 11 (3 deaths); engine-room artificers 5 (2 deaths); officers' stewards 3 (all fatal, average age 20 years); carpenter's crew 2 (1 death); boy servants 2 (1 death); cook's mate 1 (recovery); plumber's mate 1 (recovery); armourer's crew wireman 1 (fatal); trimmer 1 (recovery); boy artificer 1 (fatal).

#### (2) Remarks on Some Clinical Aspects.

**Onset.**—The mode of onset sometimes varied from the common form characterised by fever, malaise, headache, and vomiting. Eight patients when first discovered were in an unconscious condition, and 3 of these had fallen out of their hammocks; one of these, with a graze on the forehead, blood about the nostrils, and vomiting, was regarded for some days as a case of fractured base. Of the 8 cases with this apoplectiform onset, 4 proved fatal. In 4 cases in February respiratory symptoms were so well marked as to suggest pneumonia or acute bronchitis. In 1 case the prominence of abdominal symptoms gave rise to an initial diagnosis of appendicitis.

In 11 cases at least the disease began very shortly (within three days) after going on leave (6 cases) or returning from leave (5 cases), and in some instances considerable fatigue must have been entailed by the length of the journeys. In one instance the disease appeared three days after arriving on leave at Gosport from the Grand Fleet. In the 5 cases in which the disease appeared shortly after returning from leave, the question of infection when on leave arises. In 13 cases the disease occurred within three weeks of joining the Service and exposure to the trials incident to this change of life. In 3 cases the disease followed the onset of measles after an interval of about ten days. As these cases were already under observation in hospital, it is improbable that the initial mottled rash of cerebro-spinal fever was regarded as measles. In two other cases the disease attacked patients already in hospital, for a lacerated finger and pleurisy respectively. In 5 cases (4 fatal) meningitis, in which the cerebro-spinal fluid was proved bacteriologically to contain meningococci, supervened on otitis. In isolated instances drunkenness and head injury (1 case), influenza, and vaccination (4 cases) immediately preceded the onset. In 1 case pneumonia and cerebro-spinal fever co-existed. These various factors may have so reduced the bodily resistance as to enable saprophytic meningococci in the naso-pharynx to invade the system.

**Rashes** were recorded in 51, or 49 per cent., out of the 104 cases; in 41 cases the rash was petechial or haemorrhagic, and 15, or 36·6 per cent., of these proved fatal, a mortality percentage very little higher than that (35·6) of all the 104 cases. In 1 case with a petechial eruption haemorrhagic bullae appeared on the ankles four days after the rash. In 5 cases there was a macular rash with 1 death, and in 5 cases a rose rash with 1 death. The mortality of the 51 cases with rashes was, therefore, 17, or 33·3 per cent.—namely, slightly lower than the mortality of the total 104 cases. In the first year of the war, rashes occurred in 102, or 62·6 per cent., of 163 cases, and the mortality of the cases with rashes was 52 (51 per cent.), or a little lower than that (52·9) of the total 170 cases. Although a very profuse haemorrhagic rash is extremely ominous, the occurrence of a rash is not necessarily of grave significance. The rash was nearly always noticed on the first or second day of the disease.

**Herpes** was noted in 21, or 20·2 per cent., of the 104 cases; in 20 cases the herpes was on the lips; in the remaining case it was in the distribution of the nasal branch of the ophthalmic division of the fifth nerve, but the cornea was not affected. In one of the cases with labial herpes there was also cervical herpes. In 14 cases there was also an initial rash; in 2 cases the rash and the labial herpes both occurred on the second day of the disease; in the remaining cases the herpes appeared later than the rash, on an average on the fourth day of the disease, the extremes being the second and

the eighth days. In some instances the labial herpes was very profuse. Of the 21 cases 4, or 19 per cent., proved fatal; this mortality is rather more than half that (35·6 per cent.) of the total 104 cases, and thus agrees with the ancient belief that herpes in cerebro-spinal fever, as in pneumonia, is a good prognostic. In the previous year herpes labialis was noted in 35, or 21·5 per cent., of 163 cases—almost exactly the same proportion as in the present series.

**Rarer manifestations and complications.**—Ocular symptoms. Photophobia, which has been stated to be rare,<sup>2</sup> was noted in 10 cases; conjunctivitis in 5, conjunctival haemorrhage in 2, panophthalmitis with loss of an eye in 2, strabismus in 8 (5 fatal); ptosis in 3 (2 fatal); nystagmus on the second day in 1 (fatal), and von Gräfe's sign in 1. Hemiplegia occurred in 1 case and weakness of the arm in another case, both of these were fatal; facial paralysis in 1 (fatal), dysarthria in 1 (recovery), and dysphagia in 1 (recovery). Delirium tremens occurred in 2 cases (1 fatal). Pericarditis was noted in 2 cases, both of which recovered. Recent endocarditis was found after death in 1 case (*vide infra*), and transient systolic murmurs were heard in 4 cases which recovered. Status lymphaticus was found after death in 1 case. Haematuria due to haemorrhagic cystitis and pyelitis was seen in 1 case, and 1 patient had polyuria for a few days, passing 8, 6, and 4 pints of urine daily, while the temperature was about 103° F. Epididymitis without any evidence of gonorrhoea occurred once.

Synovitis was noted in 4 cases (2 fatal) on the second, fifth, sixth, and ninth days of the disease; in 2 cases the knee was affected, in 1 the ankles and wrists, and in 1 the interphalangeal joint of a finger. All the cases had a petechial or haemorrhagic eruption; this fits in with the view that when purpura and synovitis are associated, the latter is due to haemorrhages into the synovial membrane. In the case with arthritis of the wrists and ankles on the fifth day of the disease, pericarditis with synovitis of the wrists, ankles, and knees developed on the ninth day; in spite of delirium tremens recovery followed. In the first year of the war there were 8 cases (2 fatal) of arthritis. Acute otitis supervened in 2 cases, both of which recovered.

**Relapses** during treatment are said not to be uncommon and generally to occur in cases of chronic hydrocephalus which terminate fatally. There was one case proved to be of this nature in a man, aged 19, the relapse which started after nine days of convalescence being ushered in by a rigor. In one case a true relapse or brief second attack occurred seven weeks after the temperature had been normal, and was followed by recovery (*vide infra*).

Mixed infections of the cerebro-spinal fluid were reported in 3 cases; pneumococci in 1 case without any obvious focus; and streptococci in 2 cases (one an otitic case, in the other infection occurred through the lumbar puncture).

**Diagnosis.**—Only those cases in which meningococci were found in the cerebro-spinal fluid have been accepted as cerebro-spinal fever. This criterion has very probably led to the rejection of some genuine cases of cerebro-spinal fever. But no clinical manifestation is pathognomonic of the disease. Thus a haemorrhagic rash, though highly suggestive, was present in cases proved bacteriologically to be due to other infections, such as pneumococci, or to be free from micro-organisms. The latter group of cases, though unsatisfactory, must be recognised.<sup>3</sup>

A fulminating case of meningitis with a profuse haemorrhagic rash occurred on Nov. 7th, 1915, in a cadet at Dartmouth. Bacteriological examination of the cerebro-spinal fluid, which was almost clear and contained a few red blood cells and occasional polymorphonuclear leucocytes, by Fleet-Surgeon H. C. Whiteside, R.N., failed to show any micro-organisms, the cultures were sterile, and no carriers were detected among 30 contacts. There was no necropsy. A brother died in infancy from meningitis believed to be tuberculous.

Cases with meningeal symptoms, which showed meningococci in the naso-pharynx but not in the cerebro-spinal fluid have been ruled out, as they may have been meningococcal carriers with meningism due to some other cause. In

<sup>2</sup> Foster and Gaskell. *Cerebro-spinal Fever*, p. 37. 1916: Cambridge.

<sup>3</sup> Among 121 cerebro-spinal fluids from cases of meningitis in the French Army Sacquépéte, Burnet, and Weissenbach (*Bull. Acad. de Méd., Par.*, 1915, lxxiv, 103-105) found 6 with the features of Widal's "puriform aseptic meningitis," in which no micro-organisms could be found by direct examination or cultivation.

this connexion it may be pointed out that during the acute stage of cerebro-spinal fever swabs from the naso-pharynx are often negative. Out of 33 cases of bacteriologically proved cerebro-spinal fever meningococci were found in the naso-pharynx in 7, or 21·3 per cent., only. This corresponds with von Lingelshaim's figures of 635 cases of cerebro-spinal fever with 146, or 22 per cent., positive cultivations from the naso-pharynx.<sup>4</sup>

Cerebral symptoms (meningism) accompanying acute infections, such as influenza, pneumonia, enteric, otitis, malaria, may closely imitate cerebro-spinal fever, and a certain diagnosis can be made only by lumbar puncture and examination of the cerebro-spinal fluid. Even if a patient has signs of pneumonia it is possible, as shown by isolated cases in both the recent epidemics in the Navy, that there is meningococcal meningitis as well.

From other forms of meningitis lumbar puncture and examination of the cerebro-spinal fluid constitute again the most reliable method of diagnosis. Even with pre-existing otitis it does not necessarily follow that meningococcal meningitis can be excluded; for, as mentioned above, in 5 cases (4 fatal) meningitis, in which the cerebro-spinal fluid was proved bacteriologically to contain meningococci, supervened on otitis.

Difficulty might arise in the diagnosis from the meningitic form of acute poliomyelitis in which all the symptoms of meningitis may be present, but "on lumbar puncture the cerebro-spinal fluid escapes under pressure, is clear, and on cytological examination may be found to contain an increased number of lymphocytes with a normal or sometimes a diminished sugar reaction and an increased amount of albumin" (Batten<sup>5</sup>). An outbreak in Devonshire and Cornwall in 1911 of what was at first thought to be cerebro-spinal fever was shown by R. J. Reece<sup>6</sup> to be one of acute poliomyelitis, and not one of acute poliomyelitis occurring concurrently with cerebro-spinal fever. In July, 1916, there was at Shotley an outbreak of 15 cases with the clinical symptoms of cerebro-spinal fever,<sup>7</sup> but 4 only were proved to be of this nature. Among the remaining 11 cases there was one only which could possibly be regarded as an example of the meningitic form of acute poliomyelitis.

In acute osteomyelitis of the spine lumbar puncture may give exit to pus from the extradural space. This occurred in 2 cases in the Royal Navy which will subsequently be published. In neither of these were there definite symptoms of cerebro-spinal fever, but Grisel<sup>8</sup> in a review of this form of osteomyelitis states that although in some cases the symptoms of compression are quite definite and disappear when the abscess is evacuated, there are others in which the association with meningitic symptoms and septicaemia renders the diagnosis very difficult.

The sequence of events in the two following cases is, perhaps, worthy of brief mention.

Two brothers from the Fair Isle, Shetland, had measles in September, 1915, in Haslar. One developed cerebro-spinal fever 13 days after the onset of measles and died. The other, who had never been well since the attack of measles, died in Haslar three months later from tuberculous meningitis. In both cases a post-mortem examination was made.

#### (3) Summary of the Results of Treatment.

Two out of the 104 cases were discovered after death only and, therefore, were not treated for the disease; 1 case (fatal) received soamin only; and 6 cases, of which 4, or 66·7 per cent., proved fatal, had lumbar puncture only. Therefore, out of 9 cases which did not receive serum 7, or 77·8 per cent., proved fatal.

Among the 95 cases treated by some form of serum the mortality was 30, or 31·6 per cent. This result, which is in striking contrast to the results of serum treatment in the first year of the war—105 cases with a mortality of 64, or 61 per cent.—fully justifies the serum treatment of the disease, and is compatible with the widely expressed view

that the serums employed in this country during the first year of the war were largely deficient in antibodies. Flexner's serum, made under his direction at the Rockefeller Institute, New York, was not available during the first year of the war, but after the failure in this country of anti-meningococcal serum in the epidemic of 1915 the Rockefeller Institute reverted to the manufacture of the serum, and most generously placed a supply of a multivalent serum, made from 32 strains, at the disposal of the Royal Navy.<sup>9</sup> Other serums employed during this year, and not in the previous year, are Colonel Mervyn Gordon's various serums and the Pasteur Institute's multivalent serum. In the early part of the second year of the war, when the new serums were not available, Mulford's serum was given in a number of the cases, and throughout the year use was also made of the Lister Institute serum and of Burroughs Wellcome and Co.'s serum.

Of the 95 treated with intrathecal injections of serum, 60 did not receive any other form of specific treatment, and had a mortality of 18, or 30 per cent., which is a little lower than that (31·6) of the 95 cases. The remaining 35 cases received in addition one or more of the following forms of treatment: hypodermic or intramuscular injection of the serum, of vaccines or of soamin, or hexamine by the mouth, with a mortality of 12, or 34·3 per cent. In 23 out of the 35 cases the additional treatment was the simultaneous subcutaneous (or in a few instances intramuscular) injection of serum; this method was mainly adopted at Plymouth and Haslar; the mortality was 7, or 30·4 per cent. Vaccines were given in 8 cases, but did not appear, except perhaps in one or two instances, to exert any decided beneficial effect. The exact figures of the results of treatment are shown in the tabular form below:—

#### Tabular Summary of Treatment.

	Cases	Deaths.	Recoveries.

More than three-quarters of the 95 cases received serum within the first three days of the disease. From tabulation of 1211 cases Flexner found that when the serum was given within the first three days the mortality rate was 18 per cent., when between the fourth and seventh days 27·3 per cent., and when later than the seventh day 36·5 per cent., and therefore laid stress on the importance of early injection. In the 95 cases treated with serum in the Royal Navy this influence of time can also be seen:—

The results obtained by the use of the various brands of serum are shown below in a tabular statement. Flexner's serum was employed in 39 cases altogether, with a mortality of 9, or 23 per cent.; in 27 of the 39 cases it was the only serum used, with a mortality of 6, or 22 per cent.; the 12 other cases in which other serums were given as well showed a mortality of 3, or 25 per cent. The other serums were given in much fewer cases. The mortality percentage of the 14 cases that received Burroughs Wellcome and Co.'s brand (alone or combined with other serums) was slightly lower than that of the cases treated with Flexner's serum; and the 16 cases treated by Gordon's various serums alone showed an even lower mortality,

The number of occasions on which serum was given intrathecally varied in the 95 cases from 1 to 8, according to the duration of the symptoms. In some instances the improvement and fall of temperature after the injection of serum were dramatic.

Sixteen cases received one dose only, and 7 proved fatal, 6 being very acute or fulminating cases; 25 received two doses of serum (8 deaths); 22 cases three doses (7 deaths); 8 cases four doses (1 death); 11 cases five doses (4 deaths); 5 cases six doses (2 deaths); 4 cases seven doses (1 death); and 4 cases eight doses (no death). In many cases lumbar puncture was performed more often than serum was injected; in 1 chronic case in which serum was given six times, lumbar puncture was performed on 20 occasions.

Serum rashes, erythematous or urticarial, were mentioned in 22, or 23 per cent., of the 95 cases treated by serum, but may have been more frequent. The rashes and articular manifestations were practically confined to cases treated with Flexner's and Burroughs Wellcome and Co.'s brands.

Out of the 22 cases 21 received either Flexner's or Burroughs Wellcome and Co.'s serum; 12 had Flexner's serum alone, 2 Flexner's and Gordon's serum, 1 Flexner's and the Pasteur Institute's multivalent serums, 2 Burroughs Wellcome and Co.'s serum alone, 1 Burroughs Wellcome and Co.'s and Gordon's serums, and 3 Flexner's and Burroughs Wellcome and Co.'s serum (only 4 cases had this combination). The remaining case had 70 c.c. of Gordon's serum, and did not have any manifestations of serum disease except the rash. Out of the 95 cases treated with serum, 41 had Flexner's or Burroughs Wellcome and Co.'s serum, and among them rashes occurred in 21, or 51 per cent.; whereas among the remaining 54 cases treated by serum there was a rash in one case only. Six of the 22 cases with rashes also had serum hypodermically. The average amount of serum received by the cases with rashes was 65 c.c.; and the average amount received by 14 other cases which had Flexner's or Burroughs Wellcome and Co.'s serum and recovered was 70 c.c., or practically the same.

On an average the rash appeared ten days after the first injection of serum. In a case at Haslar which received one injection of 20 c.c. of Flexner's serum in a relapse seven weeks after the primary attack in Egypt, there was within a few hours an "immediate" serum rash. The patient stated

that nine lumbar punctures had been performed in the primary attack, but there is no official information as to the administration of serum.

Of the 22 cases none proved fatal, but as the serum rash occurs after an interval of about ten days, the fulminating and acute cases are obviously excluded, and this observation has no prognostic value. Six cases had both herpes and a serum rash; 9 cases an initial rash and a serum rash; and 3 cases an initial rash, herpes and a serum rash (in one case on two occasions); presumably in these instances the skin was especially prone to react.

In some cases pains in the joints without effusion accompanied the serum rash, and in two instances effusion into the joints and a temperature of 102° coincided with the rash. In 2 cases at Chatham temporary deafness occurred at the same time as a serum rash and arthralgia, and was regarded by Temporary Surgeon A. C. McAllister as a manifestation of serum disease.

Grave accidents due to intrathecal injection of anti-meningococcic serum were very rare.

In one case lumbar puncture was done directly after admission to the Royal Naval Hospital, Plymouth, and 50 c.c. of turbid fluid containing meningococci spurted out; 15 c.c. of Gordon's multivalent serum was given intrathecally and the same quantity hypodermically. Respiration stopped at once. The necropsy showed fibrinous adhesions and purulent streaks over the cerebral sulci, with but little exudation at the base of the brain. Both lateral ventricles were distended with blood-stained serum. The purulent exudate over the hemispheres suggested that the illness had last a week. In another case at Plymouth lumbar puncture on the third day of the disease gave exit to 30 c.c. of turbid fluid, and 15 c.c. of Gordon's multivalent serum were injected intrathecally; five hours later respiration stopped before the pulse. The necropsy showed fibrino-purulent exudate over the base of the brain and much yellowish fibrin over the pons and medulla, turbid and blood-stained fluid in both ventricles, oedema of the cerebellum pressing on the pons, dilatation of the right side of the heart, and recent and old endocarditis of the mitral valve. Although death did not occur until five hours after the injection of serum, this case resembles the first in the presence of blood-stained fluid in the lateral ventricles of the brain. In a third case death occurred suddenly seven hours after injection of serum and the necropsy showed distension of the lateral ventricles and acute congestion and oedema of the cerebellum pressing on the pons.

In a man who had had six lumbar punctures the site of the punctures became inflamed and death rapidly followed; at the necropsy it was found that the lateral ventricles were greatly distended with pus swarming with streptococci.

In 2 cases lumbar puncture gave rise repeatedly to severe headache, which was partially relieved when serum was injected intrathecally.

#### FOUR CASES OF HEMIPLEGIA CAUSED BY EMBOLISM FOLLOWING GUNSHOT WOUNDS OF THE CAROTID ARTERIES.

BY L. COLLEDGE, M.B. CANTAB., F.R.C.S. ENG.,  
CAPTAIN, R.A.M.C. (T.F.);  
AND  
JOHN SHAW DUNN, M.D., CH.B. GLASG.,  
LIEUTENANT, R.A.M.C. (T.O.)

A SERIES of 14 cases has recently been reported by Sir George Makins<sup>1</sup> in which symptoms of cerebral embolism followed gunshot injury of the carotid arteries. Of these cases only one ended fatally, and in it a post-mortem examination was not available, so that a complete anatomical account of the conditions could not be obtained. Four similar cases, presenting the remarkable clinical picture of a wound in the neck accompanied by hemiplegia and loss of consciousness, and all ending fatally, have come under observation in a casualty clearing station. As a necropsy was performed in every case they appear worthy of record.

CASE 1.—In this case there was a small wound on the left side of the neck, below and behind the angle of the jaw; the exit wound was also on the left side, lower down, about 1½ inches from the middle line behind. An extensive diffuse swelling appeared behind the angle of the jaw; this

swelling did not pulsate, nor was there any bruit. The patient was unconscious and stertorous, and there was hemiplegia affecting the face, arm, and leg on the right side. The patient died about 26 hours after being wounded.

On dissection of the left side of the neck there was noted a localised swelling, with haemorrhage, on the walls of the external and internal carotid arteries, just above the bifurcation of the common trunk. Two small wounds, with ragged edges, were present, one on the front of the external and the other on the back of the internal artery; these appeared to be sealed up by firm red thrombus which was entangled in projecting shreds of the adventitial tunics, and the thrombus on the back of the inner vessel exhibited a firm pea-like projection backwards. A probe which was readily passed, with light pressure, in at one opening and out at the other evidently traversed the lumina of both arteries. The vessels were removed unopened, the internal carotid being cut across half an inch from the base of the skull. Its lumen was patent at that level, but was filled by thrombus to a point just below. When fluid was poured into the common carotid artery it was observed to make its exit by the external artery, none escaping by the wounds. The lumen of the left internal carotid artery was observed to be patent also at the point where it was cut in removing the brain. The left middle cerebral vessel was normal to a point just beyond the origin of its perforating branches, but was there distended and completely blocked by a red adherent thrombus. The *Bacillus perfringens* was present in this clot in considerable numbers. There was a well-marked condition of early softening of the left hemisphere of the brain, excepting the occipital and frontal lobes. The basal nuclei were normal.

CASE 2.—In the second case there were multiple small bomb wounds, one of which was on the right side of the neck posteriorly. There was a similar non-pulsatile swelling of the neck, and the symptoms produced were similar to those in the first case. The patient died, hemiplegic on the left side, about 18 hours after being hit.

On post-mortem examination much effused blood was present in the tissues of the right side of the neck. The missile, a small fragment of bomb-casing, was seen lying under the right sterno-thyroid muscle, having penetrated the right lobe of the thyroid gland. There was a false aneurysm, about an inch in diameter, on the deep internal aspect of the right common carotid artery; its wall was formed of firm fibrin mixed with blood corpuscles. On slitting up the vessel after removal, a linear wound,  $\frac{1}{2}$  inch in length, was seen on its posterior and inner wall about  $1\frac{1}{2}$  inches below the bifurcation. A firm cylindrical thrombus was adherent to the upper end of this wound and extended upwards for a distance of  $1\frac{1}{4}$  inches, lying free in the lumen and only partially filling it. The external and internal carotids were free of thrombus as far as they could be traced in the neck, and the latter was patent also at the point where it was cut inside the skull in removing the brain. The right Sylvian artery was completely occluded by firm red thrombus just beyond the origin of its perforating branches. The right hemisphere of the brain showed well-marked early softening, with the exception of the frontal and occipital poles.

The grey matter was swollen, red, and oedematous and had a blurred margin, and contrasted with the normal left side. The basal nuclei were intact.

CASE 3.—This case was admitted within six hours of being wounded with the same symptoms of stertor and hemiplegia. The patient had been shot through the neck from side to side. On the right side there was a small wound near the posterior border of the sterno-mastoid muscle, about midway between its attachments. Arterial blood escaped freely from this wound when the dressing was removed. The right common carotid was therefore ligatured just above the omo-hyoïd; the haemorrhage was thereby arrested. The patient died without any alteration in the symptoms within 15 hours of being wounded.

In this case a false aneurysm about the size of a walnut was found on the back of the right external carotid artery just above the bifurcation of the main trunk.

(Fig. 1.) A small perforation about  $\frac{1}{8}$  inch in diameter was present in the posterior wall of the vessel at that level. The

edges of this wound were ragged and bruised, and the opening was crossed by some residual strands of adventitia with clot adherent to them. The posterior wall of the internal carotid artery was much bruised at a slightly lower level, but was not perforated. Fairly firm greyish-pink thrombus was adherent on the walls of the common carotid artery at its bifurcation, and extended  $\frac{1}{2}$  inch upwards in the lumen of the internal and  $1\frac{1}{2}$  inches in that of the external vessel, being firmly attached over the bruised areas of intima. The external carotid was the only vessel completely occluded by thrombus. Emboli were present in several branches of this vessel in the neck; the lumen of the internal carotid was free of clot from just above the injury on its wall to its termination inside the skull. The right middle cerebral vessel was normal at its origin, but all the larger branches in the Sylvian fissure were filled by portions of thrombus of the same consistency as that seen in the large vessels in the neck. The island of Reil and the motor area of the right cerebral hemisphere were softened and much congested, while the basal nuclei and the poles of the hemisphere remained normal. A few streptococci were present in films from the thrombi, and a few colonies were obtained on cultivation.

CASE 4.—This case was admitted about six hours after being wounded, already in the same condition, stertorous, and with hemiplegia affecting the face, arm, and leg on the right side. There was a wound on the left side of the neck, about  $2\frac{1}{2}$  inches above the clavicle. This patient survived for about 72 hours after being wounded.

Post mortem the left common carotid artery was found to be completely severed and the ends, filled with thrombus, were retracted so as to leave a gap half an inch in length. (Fig. 2.) The ends of the vessel were much bruised and some laceration was present for half an inch upwards on the walls of the upper segment. The thrombus in the lower segment was traced downwards to within an inch of the aorta; that in the upper extended up to the bifurcation of the common carotid, and thence for a considerable distance into the external carotid and its branches and for half an inch only into the internal carotid. The lumen of the latter vessel was patent above that level. On the base of the brain the left Sylvian artery was plugged by firm red thrombus beyond the origins of the perforating branches. This had given rise to cerebral softening, as in the previous cases.

In each of these cases the hemiplegia and cerebral disturbance were caused by occlusion of the middle cerebral artery or its branches. In all four there was thrombus present in the carotid arteries in the neck, consequent on damage of the arterial walls, and in each there were several inches of the internal carotid artery patent between that thrombus and the portion blocking the cerebral vessel. It is consequently a justifiable conclusion that the blood continued to flow for a time, at least, in the wounded vessels, and that the occlusion of the cerebral arteries occurred by embolism. Similar emboli were found in one instance in the branches of the external carotid also.

The damage to the large cervical arteries was in every case considerable. In three there was actual perforation of the wall; in the fourth the trunk was found completely severed, but this, no doubt, occurred secondarily by sloughing, after the vessel was fully thrombosed. It is remarkable that haemorrhage was so slight in these cases; in only one of them was ligature necessary.

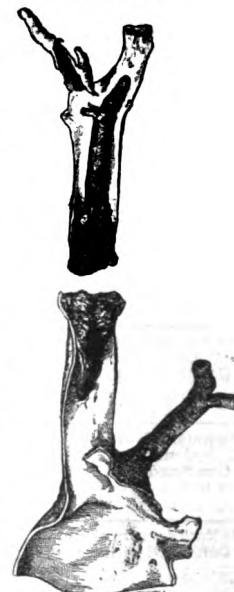

Sir George Makins draws attention to the tardy development and partial nature of the paresis as outstanding

The carotid arteries from Case 3, showing the false aneurysm and the thrombi inside the vessels. The perforation in the wall of the external carotid is quite obscured by thrombus.

(Fig. 1.) A small perforation about  $\frac{1}{8}$  inch in diameter was present in the posterior wall of the vessel at that level. The

FIG. 2.

Illustrates the complete separation of the common carotid artery, and the sealing of the ends by thrombus. The shape and arrangement of the thrombi indicate that they have formed while the blood was still circulating.

features in his series, and contrasts this with the prompt and complete hemiplegia, followed by a fatal issue in 24 to 36 hours, which may occur after ligature of the common carotid artery. In the four cases related, however, the early appearance and completeness of the hemiplegia and the rapidly fatal issue resemble the effects of ligature of the common carotid. It is natural that such cases, only surviving from 15 to 72 hours, would not reach a base hospital.

We are indebted to the Medical Research Committee for permission to make use of the two drawings by Mr. A. K. Maxwell.

## ON THE PRESENCE OF AN ACCESSORY FOOD FACTOR IN THE NASAL SECRETION

AND ITS ACTION ON THE GROWTH OF THE MENINGOCOCCUS AND OTHER PATHOGENIC BACTERIA.

(Preliminary Paper.)

BY CRESSWELL SHEARER, M.D., F.R.S.,  
MILITARY HOSPITAL, DEVONPORT.

(Report to the Medical Research Committee.)

### 1. Introduction.

In dealing with numbers of cerebro-spinal fever contacts during the recent epidemic it was noticed that the growth of the meningococcus was in some instances strongly influenced by the amount of nasal secretion transferred by the swab to the surface of the culture medium. It was found from experiment that if a trace of dilute sterile nasal secretion was added to the surface of the culture medium, it brought about a rapid growth of the meningococcus when this medium was subsequently inoculated with this germ. The growth is always many times the amount obtained on the same medium, on planting out a similar quantity of culture, in the absence of nasal secretion.<sup>1</sup>

The action of sterile dilute nasal secretion in accelerating the growth of the meningococcus would seem to be entirely in the nature of an accessory food body or vitamine, as alone this secretion is quite incapable of supporting or stimulating the growth of this germ. This conclusion is supported by its peculiar properties. It is soluble in water, slightly soluble in alcohol, and almost insoluble in ether.<sup>2</sup> It has great heat-resisting capacity, withstanding autoclaving at 120° C. and boiling in strong hydrochloric acid for 12 hours without losing strength. On filtration it always undergoes considerable adsorption, even when passed through an ordinary filter-paper, and it almost entirely disappears from any fluid when this is passed through a Doulton filter candle. All chemical manipulation, drying, precipitation, &c., appreciably weaken its power of stimulating the growth of the meningococcus.

In addition to the meningococcus and its allies, it has been shown to accelerate the growth of the pneumococcus, *B. typhosus*, *B. coli communis*, various faecal streptococci, and a number of throat bacteria. It is highly probable that it will accelerate the growth of all pathogenic bacteria when added in sterile fashion to any suitable culture material, whether solid or fluid.<sup>3</sup>

### 2. Mode of Collection of Nasal Secretion.

The nasal secretion used in the following experiments was obtained either by collection direct from the naso-pharynx by means of a suction pump, or by the employment of naso-pharyngeal swabs such as those used in the routine swabbing of cerebro-spinal fever contacts. This

<sup>1</sup> If sterile dilute nasal secretion be tested against the action of sterile dilute oral saliva in stimulating the growth of the meningococcus, it will be found that oral secretion has also some power in this respect, but this is much less than with nasal secretion. Gordon has shown (Brit. Med. Jour., June 17th, 1916, p. 849) that in the sterile state oral saliva has a marked inhibiting action on the growth of this germ. When the various mouth bacteria were removed from this secretion by sterilisation or the centrifuge, this inhibiting action immediately disappeared.

<sup>2</sup> It can be precipitated with phosphotungstic acid and neutral lead acetate, but this needs further confirmation.

<sup>3</sup> In the experiments described in the present paper the medium used is Crowe's "chocolate medium" (see THE LANCET, Nov. 20th, 1915). In other experiments similar results have been obtained with Gordon's legumen tryppagar.

latter method proved the most convenient. These swabs are made of ether-washed cotton-wool placed on the ends of flexible wires which are introduced into the naso-pharyngeal region through the mouth retracted within bent glass tubes, so that all contamination from the oral secretion is avoided. The swabs were then extracted in distilled water. It was found that quite a considerable amount of secretion could be obtained in this way. This will be referred to in the following experiments as "dilute" nasal secretion in distinction to that collected "undilute" direct from the mucous membrane of the naso-pharynx, by means of the pump.

### 3. The Preparation of Various Extracts of Nasal Secretion.<sup>4</sup>

(a) General treatment in the preparation of aqueous, alcoholic, and ethereal extracts. The cotton-wool was removed from the swab wires and covered with the solvent in glass-stoppered specimen tubes of suitable size, using 1-2 c.c. for each swab. After standing for 24 to 48 hours, the liquid was removed with a pipette, and filtered through a 5 c.c. Swedish acid-extracted filter-paper. Aqueous extracts which were further treated, and all alcoholic and ethereal extracts, were evaporated to dryness on a tepid water-bath at a temperature of about 60° C., the basin being removed before it was absolutely dry when water was the solvent, and then taken up in distilled water, 1 c.c. of water being allowed for each swab extracted.

(b) Preparation of hydrolysed nasal secretion. 3 c.c. of undilute nasal slime was heated with ten times its volume of strong HCl in a test-tube standing in boiling water for six hours. More HCl was added to make up for the loss by evaporation, and the heating continued for six hours more. The solution, which was faintly yellow, was transferred to a porcelain dish and the excess of acid was evaporated off on the water-bath with the continual addition of water. When nearly all the acid had been removed the remainder was dried at a low temperature, dissolved in 7 c.c. of water, and made faintly alkaline to litmus paper with N/10 NaOH, about 5 c.c. being necessary.

All the extracts before being sealed up in vaccine tubes were tested and their alkalinity adjusted as closely as possible to Ph. = 7.35 of Sorenson's scale. The extracts after being sealed up were finally sterilised at 55° C. for an hour. All manipulation of the extract was conducted in beakers of Jena glass, or Berlin porcelain or platinum, and great care was taken to have all glassware, especially the slides used for mixing the dilutions, clean and free from any chemicals. The distilled water used was redistilled from glass several times.

### 4. Method of Testing the Action of Extracts.

The action of the various extracts of nasal secretion in stimulating the growth of the meningococcus and other bacteria was tested by making a number of dilutions of the germ in the extract, and planting out each dilution separately and comparing their growth, with a similar quantity of the same emulsion diluted in a similar manner in distilled water or Ringer's solution, and planted out in the same way. It was found after several trials that distilled water offered the best form of control. In the following experiments care was always taken to make the control dilution first and to plant it out immediately. Thus all harmful action of distilled water on the germ was minimised as much as possible.<sup>5</sup> Where typhoid and coli organisms were used all emulsions and controls were made in Ringer's solution.

A large number of methods of dilution were tried. The one found most useful consisted in taking up in a calibrated pipette, finely throttled to ensure accurate measurement, nine volumes of the fluid to be tested, each volume representing 25 c.mm. of liquid. They were then spread out separately on sterile slides. Then with a smaller pipette, also throttled, 5 c.mm. of a standard emulsion<sup>6</sup> of the meningococcus (5000 million to the c.c.) in Ringer's solution, was drawn up. This was added to the first of the 25 c.mm. volumes on the slide and thoroughly mixed by drawing it up to a fixed

<sup>4</sup> For the proper preparation of the extracts the Medical Research Committee have kindly placed the services of Mr. D. Matthews at my disposal.

<sup>5</sup> I have shown elsewhere (THE LANCET, 1916, II., 902) that the meningococcus is peculiarly resistant to the hypotonic action of distilled water. I have shown that it can withstand its action for many hours without experiencing any apparent ill-effect.

<sup>6</sup> In speaking of a "standard emulsion" of the meningococcus in the following experiments it will always be understood that one in Ringer's solution of the strength of 5,000,000,000 cocci to the cubic centimetre is meant.

mark each time in the process of mixing. Then from this 5 c.mm. was taken up and transferred to the second 25 c.mm. volume and the mixing repeated. This procedure was gone through in succession with each of the nine volumes. Thus in the end a series of nine successive dilutions of the germ were obtained. Then by means of a fine sterile camel-hair brush or fine capillary tube, a certain quantity of each dilution was transferred in turn to the surface of the culture medium, commencing with the highest and gradually working down to the lowest dilution. The quantity transferred could be accurately measured when a capillary tube was used, but when a brush was employed it was only roughly the same in each instance. The dilutions were spread on the surface of the culture medium by dipping the brush in one of them and then drawing it rapidly across the surface of the plate. This operation was repeated in turn with each of the dilutions. Thus a series of nine parallel lines were obtained on the plate, each representing a particular dilution of the germ in the solution to be tested.<sup>7</sup>

##### 5. Experiments.

**Experiment I.** (Figs. 1 and 2).—A "standard" emulsion of an old laboratory culture of meningococcus (Littledale) was made up in Ringer's solution. 5 c.mm. of this emulsion was added to 25 c.mm. of distilled water and of an aqueous extract (see under Sec. 3a) of dilute nasal secretion respectively, and diluted down through nine successive dilutions, and planted out by means of a brush as described under Sec. 4. Thus nine parallel lines, as shown in Figs. 1 and 2, were obtained on the plates,<sup>8</sup> one representing the dilution in nasal secretion extract and the other the control dilution in distilled water. Line No. 1 contains the fewest number of germs, while line 9 contains the largest number. Each line contains very roughly the same number of germs as the corresponding line on the other plate. The plates were incubated at 37° C. for 24 hours and then taken out and the resulting growth photographed. The photographs show the plates reduced to half natural size.

In Fig. 1, showing the dilution in distilled water, little growth has taken place except on lines 7, 8, and 9. In the same degree of dilution in aqueous extract of dilute nasal secretion, Fig. 2, considerable growth has taken place on all the lines, and is confluent in the case of lines 7, 8, and 9. A comparison of the two photographs gives a rough idea of the accelerating action of nasal secretion on the growth of the meningococcus.

It was immaterial whether, in this experiment, Ringer's solution was substituted for distilled water in the control dilutions to obviate all possible harmful action of the distilled water; the result was the same. There is possibly a slight increase in the growth obtained in the control, due to the use of Ringer's solution, but this increase was not sufficient to alter the main result of the experiment. There was always a preponderating growth with nasal secretion extract.

**Experiment II.** (Figs. 3 and 4).—In this experiment, instead of an old laboratory culture being used as in Experiment I., a freshly isolated strain of the meningococcus (Walters) was taken. This had been obtained from the spinal canal of a cerebro-spinal fever patient about a week previous. In this instance the dilutions of a "standard" emulsion were made as before in distilled water and nasal secretion (aqueous extract), but instead of a small quantity of each dilution being transferred to the plates by means of a brush, each dilution containing 30 c.mm. of fluid was transferred by means of a fine capillary pipette to the surface of the culture medium. Thus, instead of a series of lines, a series of drops or blebs were obtained representing 11 consecutive

dilutions of the germ in distilled water and nasal extract respectively.

A comparison of Figs. 3 and 4 shows the accelerating action of the nasal secretion extract over that of the distilled water one. The figures, however, hardly bring out the proper difference between them, as the spreading of the drops on the surface of the medium has been irregular. Actual inspection of the plate, Fig. 4, shows, for instance, that dilution No. 11, which contains the fewest number of organisms, is very thin and spread out, while No. 1, which contains the largest number of germs, is very heaped up and thick, a condition which is not very obvious from the photograph.

The comparison of dilutions 7-11 of Fig. 4 with the same dilutions in Fig. 3 dispels any doubts as to the accelerating action again of nasal secretion in this experiment.

**Experiment III.**—In this experiment it was sought to find out the amount of accelerating action nasal secretion extract brought about on the growth of the meningococcus when growing in a fluid broth medium and not a solid medium as in the former experiments. To two small vaccine tubes containing each 2 c.c. of sterile glucose litmus broth 5 c.cm. of "standard" emulsion of meningococci (Walters) was added. To one of the tubes in addition 5 c.cm. of an aqueous extract of dilute nasal secretion was added. The tubes were then incubated for 48 hours at 37° C. At the end of this time the tube that had received the nasal secretion in addition to the meningococci had entirely lost all trace of pigment, while that which was without the extract still retained a certain amount of reddened litmus pigment. The tubes were then carefully shaken up to ensure an even distribution of the cocci, and counts were made of a certain volume of fluid from each tube. This showed that there was roughly eight times the number of cocci per c.mm. in the tube with the nasal extract as compared with that without it.

**Experiment IV.**—In this experiment an attempt was made to see if prolonged boiling of aqueous extract of dilute nasal secretion had any action in destroying its power to stimulate the growth of the meningococcus. 4 c.c. of an aqueous extract of dilute nasal secretion was boiled continuously for five hours, distilled water being added from time to time to keep it at the same volume. (See Sec. 3 b.) It was then tried out as before, against some of the same aqueous extract unboiled, with a "standard" emulsion of meningococcus (Littledale). It was found that the boiling had had but little or no effect in weakening the action of the nasal secretion.

**Experiment V.** (Figs. 5, 6, and 7).—In this experiment hydrolysed nasal secretion prepared by boiling undilute nasal slime with strong hydrochloric acid for 12 hours (as described in Sec. 3 (b)) was tested against the action of the same nasal secretion untreated with HCl. Dilutions of a "standard" emulsion of a freshly isolated culture of meningococcus (Lake) were made in distilled water (control), nasal slime, and nasal slime hydrolysed, respectively. These were planted out on a plate by means of a brush in the usual way.

Photographs 5-7 show the result of this experiment. It will be seen that the hydrolysed nasal secretion is as active in accelerating the growth of the meningococcus as the same secretion untreated (Figs. 6 and 7). The action of both hydrolysed and the non-hydrolysed secretion in accelerating growth is well shown by comparison of these plates with that planted out with the control dilutions in distilled water. This experiment has been repeated a number of times with different strains of meningococci and always gave the same result.

**Experiment VI.** (Figs. 8-11).—To determine the relative power of a plain alcoholic extract of dilute nasal secretion, as compared with a plain aqueous extract and an ether extract of the same in stimulating the growth of the meningococcus. Dilutions of a standard emulsion of meningococcus (Paul) were made as before. The diluents were distilled water (control), aqueous extract of dilute nasal secretion, plain alcoholic extract of dilute nasal secretion, and ether extract of the same. Figs. 8-11 show the resulting growth obtained after 24 hours' incubation at 37° C. Comparison of Fig. 10 with Fig. 9 shows the action of a plain alcoholic extract of dilute nasal secretion to be almost as active as that of an aqueous one, while comparison of both these figures, with the control in distilled water (Fig. 8) shows the amount of acceleration in growth produced.

The conclusion drawn from this experiment was that the active principle in nasal secretion which accelerates the

<sup>7</sup> If we commence with an emulsion of 5000 million meningococci to a cubic centimetre, and make nine consecutive dilutions of 5 parts in 30 in each dilution, then theoretically we should expect to find in each of the nine dilutions the number of cocci per cubic centimetre as follows:—

Dilution.	Cocci.	Dilution.	Cocci.
1 .....	833,000,000	6 .....	170,000
2 .....	139,000,000	7 .....	18,000
3 .....	23,000,000	8 .....	3,000
4 .....	4,000,000	9 .....	500
5 .....	640,000		

These numbers were never actually approached in the following experiments, as the pipettes and brushes were not sterilised in passing from one dilution to another.

<sup>8</sup> The numbering of the experiments is only for the convenience of the present paper; many of the experiments described have been repeated a great many times.

<sup>9</sup> All the experiments described in this paper refer to implantations on Crowe's "chocolate medium."

EXPERIMENT VII.—*B. typhosus.*

FIG. 10.—Dilutions in alcoholic extract of nasal secretion.  
FIG. 11.—Dilutions in ether extract of nasal secretion.

FIG. 12.—Showing the action of dilute nasal secretion in stimulating the growth of *B. typhosus*. The upper half of the plate shows the dilutions of the germ in Ringer's solution, while the lower half shows the dilutions in dilute aqueous extract of nasal secretion.

Cultures (one-third natural size) photographed after 24 hours' growth. The streaks are to be read from above downwards.

growth of the meningococcus is soluble in distilled water, less so in alcohol, and almost insoluble in ether.

*Experiment VII.* (Fig. 12).—To determine the action of nasal secretion extract on the growth of *B. typhosus*. In Fig. 12 the upper half of the plate has been planted out in the usual way with dilutions of an emulsion of *B. typhosus* in Ringer's solution; in the lower half, with dilutions of the same emulsion in aqueous extract of dilute nasal secretion. Fig. 12 shows that a much more abundant growth took place on that half of the plate which received the nasal secretion.

The conclusion drawn from this experiment was that the growth of *B. typhosus* is accelerated in a similar manner to that of the meningococcus by an aqueous extract of dilute nasal secretion.

Similar results were obtained in experiments with the following germs:—*Streptococcus zymogenes*, *Micrococcus pharyngeus flarus*, *pneumococcus*, and *B. coli communis*.

#### Conclusion.

The outstanding results of the foregoing experiments show that in nasal secretion there is present some body which greatly accelerates the growth of the meningococcus on an artificial culture medium. Alone it is incapable of acting as a food or stimulant to the growth of this germ. It is soluble in water, less so in alcohol, and very insoluble in ether. It has great heat-resisting power, being able to resist prolonged boiling for many hours. It is not destroyed by boiling in the presence of strong hydrochloric acid for twelve hours. In addition to the meningococcus it also stimulates the growth of many other pathogenic germs.

## A NOTE ON THE CAUSE AND PREVENTION OF TRENCH FOOT.

By C. NEPEAN LONGRIDGE, M.D. VICT., F.R.C.S. ENG.,  
M.R.O.P. LOND.,  
LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

No one who has had an opportunity of observing many cases of trench foot, particularly in the later stages of the disease, can have failed to be struck with certain characteristics presented by it. The lesions are indolent, slow to heal, and prone to break down again on the slightest provocation. The scar tissue formed is weak and ulcerates easily. Indeed, the whole picture of the disease reminds one irresistibly of the trophic sores appertaining to diseases of the central nervous system. I wish to set forth in this paper my reasons for thinking that trench foot is an affection of a trophic nature.

Some three years ago a book on electro-pathology was published by Mr. A. E. Baines, a distinguished electrical engineer. Space does not permit me to give an account of the far-reaching vista of promise which this little-known work has opened up to medicine. An abler pen than mine has recently put the whole matter before the profession. Let it suffice to say that Mr. Baines believes that the brain, and possibly the cord, is the seat of electrical generation, and that the current so generated is carried to the tissues by means of the nerves, which to the electrician's view are nothing but insulated cables. Here we have the trophic influence of physiology and medicine, that vague generalisation which from our student days we have been content to accept without questioning. Mr. Baines has shown us how to measure and modify this trophic influence, and I venture to predict that in the future his name and fame will equal that of those illustrious ones, Simpson, Lister, and Koch, as benefactors of the human race. This is no mere discovery of an isolated fact in medicine. Many a patient worker has given his brick, his hard-wrought stone of research to the building of the sacred fane of *Asculapius*. As is perhaps fitting and proper for an engineer, Mr. Baines has come and shed a flood of light in our temple. For he has given us a fundamental principle.

The dominating factor in the conditions under which trench foot occurs is wet. When a man is standing for days on end in water and liquid mud, his boots, socks, and the skin of his feet and legs become soaked. As is well known, the electrical resistance of the skin is enormously diminished when the skin is wet. Under these conditions a gradual leakage of electricity to earth takes place from the feet. Other things being equal, electricity will always leak

from a point in preference to a plane surface, which accounts for the fact that the toes are most affected. This leakage deprives the cells of the foot tissues of their trophic influence and they die. Hence the lesions of trench foot.

Local leaks of electricity may be detected by a suitable galvanometer. One pole of the galvanometer should be connected to a silver plate about the size of a florin, which is fixed in the centre of the patient's forehead; there is no special reason for fixing it on the forehead except that it is the most convenient spot in the middle line of the body. The other pole is connected to a contact plate mounted in an insulated handle so that the contact or electrode can be placed on any portion of the body it is desired to test. Before testing it is necessary to "earth" the patient in order to dissipate any induced charge of electricity of which he may be the host. If this is not done the patient's own intrinsic current may be swamped by charges he has picked up from trams, electric trains, or other sources. With both poles in contact with the body the galvanometer will give a deflection. When leakage is taking place from any particular area a high and rapid deflection is noted. I have been examining and treating various cases on Baines's principles for a matter of about two years, and have found such a leakage taking place from the feet and legs of soldiers suffering from trench foot whom I had under my care last spring. Moreover, the results I obtained by treating these cases by dielectric oil were better than the results obtained by any other method I tried. I also made a few experiments bearing on this subject.

*Experiment 1.*—With the aid of Miss Flecker, at the Ladies' College Physical Laboratory, Cheltenham, I estimated the electrical resistance of a piece of oak tanned sole leather 3 inches long by 1 inch wide. We found that when dry the resistance was practically infinity. When wet the resistance is that of the fluid the leather has soaked in.

*Experiment 2.*—One pole of the galvanometer was connected to an electrode which could be held in the hand. The other pole was connected by an insulated cable to a copper plate imbedded in the earth. Another insulated cable was connected at one end to the metal pipe supplying water to the house, and at the other end to a brass rod of 1 inch section. After earthing myself I held the brass rod in one hand and the electrode in the other, and obtained a rapid off-scale deflection, showing, firstly, that an electric current was coming from my body; and secondly, that the earth connexions were working properly, for the current passed out by one hand through the brass tube to the water pipe, thence about 20 feet through the earth to the copper plate, and through the galvanometer to the other hand, so completing the circuit.

*Experiment 3.*—The brass tube was then laid on the floor which was covered by a thick carpet. I held the electrode by one hand and put both feet on the brass tube. I wore ordinary boots which were dry. No deflection was obtained because the dry leather soles of my boots insulated me from the earth. I then took my boots off and put my bare feet on the tube and obtained an off-scale deflection.

*Experiment 4.*—Next day was wet and I walked about half a mile so that the soles of my boots, which were free from holes and metal nails, became wet. On holding the electrode in one hand and placing my feet on the brass tube, a rapid off-scale deflection occurred, showing that current was passing through my boots to earth.

*Experiment 5.*—The pole of the galvanometer connected to earth by the copper plate was disconnected. It was reconnected to a hand electrode exactly like the one previously used, so that the galvanometer was now connected to the hand electrodes only. After the necessary earthing process, I held the electrodes in the hands and obtained a deflection which remained steady at 170 mm. I then placed my feet, still in wet boots, on the brass tube and awaited results. The light on the scale very slowly began to recede towards zero. I repeated this experiment several times. The light never remained at zero, but if it got as far went over to the other side of the scale, and generally registered 40 to 60 mm. I take this as evidence that electricity was gradually leaking out of my body to earth, through my wet feet. One would not expect the light to register zero as there is continuous generation of electricity in the body. In view of these experiments, the grandmotherly advice we have so often received, not to stand about in wet boots, takes on a new and important significance which ought to claim our belated respect. They also to my mind afford evidence that trench foot is probably caused by long-continued leakage of electricity from the feet.

I noted that Dr. Leonard Hill had advocated rubber boots and greasing of the feet for the prevention of the disorder, recommendations with which I cordially agree. I sent to him in the spring a note about my own experiments, and

received from him a courteous letter thanking me for my "ingenious speculations," but countering me with the query "What about fishes, fishermen, and Channel swimmers?" When truth is really truth the most knock-out objections often end in being pillars in its support. Just as the vagaries of radium appeared to undermine the whole structure of physical science, and now form an additional proof that the foundations of that science have been well and truly laid, so Dr. Hill's objections assist my argument. For fishes are provided with a dielectric coat of mucus; I never heard of fishermen who had wet feet as long as the men in the trenches: and Channel swimmers always try to emulate the fish by rubbing themselves with a dielectric coat of oil. Their idea is to keep out the cold—it is really to keep in the electricity of their bodies; improved methods of accomplishing this result will at once suggest themselves to anyone acquainted with Baines's work.

The experience of officers at the front is that trench foot can be prevented. I am certain it can, but it can only be done, firstly, by keeping out the wet, and, secondly, by keeping up the electrical resistance of the skin of the feet. The feet should be thoroughly greased, and by far the best grease to use is the dielectric ointment which is now an article of commerce. It is interesting to note that our French colleagues are suggesting the use of ambrine for trench feet; they have had very good results with it in burns, but it is used empirically without appreciation of its dielectric action. I doubt if anything could improve on the results obtained by dielectric oil in cases of burns.

Rubber boots if worn for any length of time cause the feet to perspire too freely. White Robertson in the paper referred to above has shown that the soles of the feet and palms of the hands are parts which are designed to sweat freely and through which the normal escape of electricity to earth mostly takes place. The disadvantage of rubber boots is that owing to the excessive perspiration they cause the skin of the feet is liable to become sodden and so lose its electrical resistance. Soaking the boots, socks, and puttees in oil is the alternative I suggest for rubber boots. Any thick oil would do as a preventive; kitchen fat rendered with olive oil or cotton-seed oil might be tried, but I think that the skin of the feet should be rubbed with a dielectric grease. If signs of trench foot should develop in cases where these precautions have not been efficiently carried out, the best treatment is to wrap the foot and the whole of the lower part of the limb as far as the knee-joint in gamgee tissue soaked in dielectric oil. I have seen enough of this treatment to justify the assertion that no serious case of trench foot necessitating amputation need take place.

the right lung. Over the apex of the right lower lobe the signs were somewhat similar but less pronounced. The left lung seemed healthy. There were no cardiac murmurs and the urine was normal. His chief complaint was of the flitting pains across his chest, which were generally most severe at night. Cyanosis, first noticed in the lobules of his ears early in October, gradually spread to the face, while there was none of the extremities. With the deepening of the lividity there developed oedema. His lower eyelids became heavy with watery bullae and his neck swollen, measuring on the day of his death 17 inches at the level of the thyroid cartilage, while in health he wore a collar of 15½ inches. The external jugular veins stood out prominently. The superficial veins of the chest became distended, more markedly on the left side, and running along the left costal margin corresponding to the attachment of the diaphragm was a network of dilated venules. The superficial abdominal veins were not distended. There was no swelling of the arms or legs. The glands at the root of the neck and in the axilla were enlarged. The pupils were equal and so were the radial pulses. Towards the end he became very drowsy, even falling asleep during conversation. His breathing became stertorous and he died on Nov. 1st. A differential blood count made after the cyanosis became evident showed polynuclears 92 per cent., lymphocytes 3 per cent., and mononucleate (large) 5 per cent. The Arnett count gave a ratio of 46 to 54. The temperature was normal until the last few weeks, when there was a slight rise, but not beyond 99.4° F., with a small daily variation. At the post-mortem examination it was found that a large solid mass filled the superior and the posterior mediastinum. The pleura covering the right lung was firmly adherent. The upper lobe of the right lung was almost entirely invaded by tumour, and there was involvement of the upper portion of the lower lobe. The left lung and its pleura were healthy. Microscopically the tumour was seen to be a lympho-sarcoma. A section showed the growth destroying the wall of the superior vena cava and projecting into its lumen.

The case is of interest in showing the difficulties attendant on the making of a diagnosis of phthisis in the absence of tubercle bacilli from the sputum. The blood examination was helpful, although, unfortunately, a count was not made until the later stages of the illness. The high polynuclear count suggested an acute mixed infection if the case were really tuberculous, but the nearly normal temperature negatived such an infection. The Arnett count was practically normal, while, according to the findings of different observers, an active tuberculosis causes a definite deviation to the left.

For permission to publish this case I am indebted to Dr. C. F. Walker, medical superintendent of the Westmorland Sanatorium.

Grange-over-Sands.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### A CASE OF SARCOMA OF THE MEDIASTINUM INVADING THE LUNG.

BY A. G. M. GRANT, M.D. EDIN., D.P.H.,  
FIRST ASSISTANT MEDICAL OFFICER, WESTMORLAND SANATORIUM,  
GRANGE-OVER-SANDS.

THE following case illustrates the points of resemblance between phthisis and malignant disease of the lung. On the admission of the patient to the sanatorium seven weeks before his death the clinical picture was in the main one of phthisis, but in the later stages the distinguishing features of thoracic tumour manifested themselves and suggested malignancy.

A man, aged 55 years, was admitted to the Westmorland Sanatorium on Sept. 13th, 1916, with a history of good health until the previous April when he first complained of radiating pain in the front of his chest, followed shortly afterwards by cough and expectoration, which compelled him to give up work in July. His sputum was copious and mucopurulent, of a yellowish brown colour, and well intermingled with blood. No T.B. were found. Examination showed deficient expansion, dullness, high-pitched breath sounds almost tubular in character, and increased vocal resonance over the upper lobe of

#### A CASE OF LARGE OMENTAL CYST IN A CHILD.

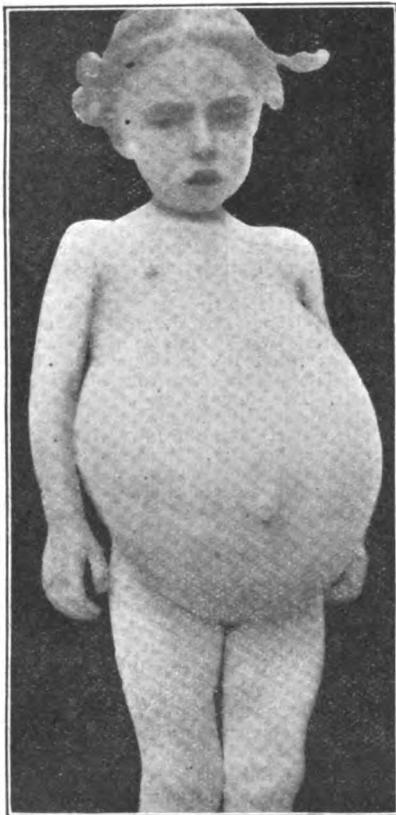

BY FREDERICK C. PYBUS, M.S. DURH., F.R.C.S. ENG.,  
SURGEON TO THE HOSPITAL FOR SICK CHILDREN; ASSISTANT  
SURGEON TO THE ROYAL VICTORIA INFIRMARY,  
NEWCASTLE-ON-TYNE.

OMENTAL cysts are sufficient rarities to warrant the publication of individual examples. The following notes are those of a patient in the Hospital for Sick Children, Newcastle-on-Tyne.

The patient, a girl, aged 4 years, was admitted to hospital in June, 1915, supposed to be suffering from tuberculous peritonitis. She was the only living child of a family of three, the mother having died of phthisis. It was noted that the child's abdomen had been swollen since she was 9 months old. She had been tapped on two occasions at the ages of 18 months and 2 years, but on each occasion the fluid gradually returned. After admission she was again tapped, six pints of fluid being removed. A few weeks later she developed scarlet fever and was transferred to the fever hospital. The photograph shows the condition of the abdomen at this period.

She was readmitted to the hospital in May, 1916. The circumference of the abdomen was 29½ inches. She was tapped twice shortly after admission, two pints being removed on each occasion. The fluid was of a slightly reddish colour and contained cholesterol crystals. I was then asked to see her by Dr. J. E. Dainty, who suggested that the condition might be a cyst and that abdominal exploration would be advisable. She was transferred to my ward and an operation was carried out in June, 1916. The

abdomen was opened above the umbilicus. A thin-walled cyst was found occupying the larger part of the abdomen. Three fine strands passed from the cyst to the abdominal wall, which I regarded as due to the previous aspirations. The cyst was tapped and drawn outside the abdomen. It was thin-walled, partially loculated, and situated in the great omentum. It was readily stripped from the omentum except at one part where the omentum was torn, and its upper part had to be peeled from the greater curvature of

Omental cyst in a girl of 4 years. Circumference of abdomen, 29½ inches.

the stomach. The omentum was repaired, completing the anterior wall of the lesser sac. The abdomen was then closed. The child made a perfect recovery and was discharged a fortnight later. The cyst was of the size of a large football. The exact quantity of fluid was not measured, but half-filled an ordinary pail. The cyst was occupied by a thin brownish fluid containing cholesterolin crystals and was partially divided into several loculi. Portions of the great omentum were removed with the cyst and remain adherent to its wall. Microscopic examination of its wall revealed no epithelial layer, so that it is difficult to account for its origin.

Newcastle-on-Tyne.

**DONATIONS AND BEQUESTS.**—The Chelsea Hospital for Women has received from the trustees of the Zunz Bequest £5000, being the balance of the £10,000 generously promised by the trustees towards the rebuilding of the hospital.—The trustees of the late Miss Marjory Shanks Schaw, of Glasgow, have given £60,000 to the Western Infirmary, £40,000 to the Victoria Infirmary, Glasgow, and £10,000 each to the Royal Samaritan Hospital for Women, the Royal Hospital for Sick Children, the Royal Maternity and Women's Hospital, and the Association for the Relief of Incurables, all Glasgow institutions.—The late Mr. John Sloughgrove, of Purliegh, has bequeathed £150 to the Essex County Hospital, £200 each to the Royal London Ophthalmic Hospital and the Reedham Asylum for Fatherless Children, £300 to Dr. Barnardo's Homes, and £250 each to the London Hospital and the Eastern Counties Asylum for Idiots.—The late Miss Isabella Mary Peploe-Smith, of Onslow-square, S.W., bequeathed £500 each to the Cancer Hospital, Brompton, the Consumption Hospital, Brompton, and the Society for the Prevention of Cruelty to Animals.

## Medical Societies.

### ROYAL SOCIETY OF MEDICINE.

#### SECTION OF HISTORY OF MEDICINE.

##### *Casanova's Mémoires.*

A MEETING of this section was held on Dec. 20th, 1916, Dr. NORMAN MOOKE, ex-President, being in the chair.

Dr. J. D. ROLLESTON read a paper on the Medical Interest of Casanova's *Mémoires*. He said that as a child Casanova appeared to have suffered from adenoids and small-pox. His sanguine temperament predisposed him to epistaxis, to which he was subject from childhood, and to piles, which he first developed during one of his imprisonments. From early adult life onwards he had attacks of fever, possibly malarial in origin, and at the age of 45 he had a severe attack of lobar pneumonia. He had numerous attacks of venereal disease—gonorrhœa and soft chancre, and possibly syphilis, as might have been expected from his own account of his life. He apparently sought medical advice on each occasion, and no sequelæ resulted. In old age he suffered from gout, and his death was probably due to septic absorption, secondary to enlargement of the prostate. Originally intended for the medical profession, Casanova retained throughout his life his interest in medicine, as is shown by his descriptions of disease, his criticism of doctors' dogmatic opinions on medical subjects, his successful simulation of various maladies, and his incursions into the field of therapeutics.

## Reviews and Notices of Books.

### *Diseases of the Umbilicus.*

By THOMAS S. CULLEN, M.B., Associate Professor of Gynaecology, Johns Hopkins University. With 269 illustrations. London and Philadelphia : W. B. Saunders Company. 1916. Pp. 665. Price 35s. net.

THIS volume contains a complete account of the various diseases affecting the umbilicus and the urachus. Not only has Dr. Cullen collected all that is known about these conditions, but he has also carefully recorded the more important cases, so that his work will be invaluable for reference to any future workers and serve as a foundation on which they may build.

It would seem hardly possible that so many pages could be needed to describe the diseases of so small an area of the body as the umbilicus. This book, however, deals not only very fully with all the known diseases of the navel, but also with such other matters as the omphalomesenteric duct and vessels, Meckel's diverticulum, and the urachus. The importance of the embryology of the umbilicus is very considerable because so many of the lesions are due to a partial or complete lack of closure of the omphalomesenteric duct or of the urachus. The section devoted to this subject is extremely clear and is illustrated by a very fine series of drawings by Max Brödel. The many interesting and instructive points which a detailed study of the anatomy reveals are well set out in Chapter II., and the four plates showing the different forms of the umbilicus will be a revelation to those who have never studied this region particularly. Umbilical infections and haemorrhage in the new-born child happily have lost the importance they once had, but an account of many of the old epidemics is given by the author and their relation to infections of the umbilical stump clearly shown. A large number of cases of the curious tumours formed by remnants of the omphalomesenteric duct, the so-called umbilical polyp, are collected and given in full, while the chapters dealing with a patent omphalomesenteric duct and prolapse of the bowel through such a duct are most interesting. As the author rightly points out, when a small umbilical polyp is noted after the cord has come away, the probable persistence of other portions of the omphalomesenteric duct, such as a Meckel's diverticulum or a cord from the mesentery to the umbilicus, must be remembered and the added possibility of intestinal obstruction developing later in life explained to the parents. It is interesting to find that most of the cases of so-called dermoids of the umbilicus turn out on further investigation

to be nothing more than inflammation due to the irritation of an umbilical concretion, the presence of caseous material and wool from the patient's clothing having led to an erroneous diagnosis in many of the cases. Records of cases of Paget's disease, diphtheria and syphilis of the umbilicus are given, and also numerous cases illustrative of the escape of intra- and extra-abdominal fluid, mostly pus, through the umbilicus as well as cases of umbilical fistulae. Among the most curious of all the conditions described is the series collected by Dr. Culley of umbilical tumours containing uterine mucosa or remnants of Müller's ducts, in reality adenomyomata of the umbilicus. It was a case of carcinoma of the umbilicus which first led the author to a study of the whole subject, and the chapter on that condition contains the records of many cases of both primary and secondary carcinoma of this region. These clinical histories show that the development of a small, hard umbilical nodule in a patient at or beyond middle age should at once raise suspicion as to the presence of some intra-abdominal malignant growth, and if there be symptoms suggestive of carcinoma of the stomach or gall-bladder the probability will become almost a certainty. Urachal anomalies, such as cysts, large and small, simple and infected, patency of the urachus and urinary fistulae, may give rise to a great deal of inconvenience and present clinical features often difficult of diagnosis. They are all, however, very fully described by the author, and a reference to this work should assist in clearing up many diagnostic puzzles of this nature.

The whole is a monument of industry and skill, and will form the most complete and important work on this subject for many years to come.

#### *Tratado de Pediatría.*

Por el Dr. MARTINEZ VARGAS. Tomo I., Fundamentos de la Pediatría. With 12 figures and 27 plates. Barcelona: J. Vives. Pp. xiv.-959.

Dr. Martinez Vargas, who is professor of paediatrics in the University of Barcelona, founder and President of the Spanish Paediatric Society and member of many learned societies, both Spanish and foreign, is to be warmly congratulated on this first volume of what, if the standard here set is maintained in the two further volumes promised, will be a really monumental contribution to the study of his subject, using the word in its widest and most comprehensive sense. Dr. Vargas connotes by paediatrics not merely the study of the diseases of children from the standpoints of pathology, diagnosis, and therapeutics, but also a fairly detailed consideration of the anatomy, physiology, hygiene, and vital statistics of infancy and childhood; he pays some attention to the history of paediatrics, its literature, and its development in civilised countries throughout the world.

In the first chapter, headed "General Considerations" (*Generalidades*), Dr. Vargas defines paediatrics as that department of medicine which takes for its subjects of study infancy and childhood in such of their aspects and relations as are of special interest to the physician. He goes on to discuss the limits of the subject and some of the special characteristics of infancy and childhood, their vulnerability to morbid influences on the one hand, their quick reaction and recovery on the other, the readiness with which anaemia comes on in any complaint tending to chronicity, the rapidity with which, in serious illnesses, exhaustion both supervenes and is recovered from, the influence of growth, and the preponderance of the lymphatic system. Next he deals with the anatomy of infancy and childhood, when the thymus gland, its anatomy and special functions are discussed fully. Then, after describing the special physiology of the new-born infant, he passes to a detailed consideration of the subject of infant feeding. This section is of especial value and is abreast of our present knowledge of the subject. Sections on dentition and growth complete the consideration of the special physiology of children, and the remainder of this section is devoted to digestion, respiration, and other functions common to the child and the adult. For the rest, the book deals systematically with the hygiene, pathology, and therapeutics of childhood.

The author's treatment of his subject is thorough and is characterised by a lucidity and sureness of touch which are the obvious fruit of wide knowledge and practical experience. The publisher is to be congratulated on the excellence of the plates and figures illustrating the work.

#### LIBRARY TABLE

*Infection and Immunity: A Text-book of Immunology and Serology for Students and Practitioners.* By CHARLES E. SIMON, B.A., M.D., Professor of Clinical Pathology at the College of Physicians and Surgeons, &c., Baltimore. Third edition, revised and enlarged. Illustrated. London: Baillière, Tindall, and Cox. 1916. Pp. 352. Price 14s. net.—Dr. Simon's practical and clearly written book has been brought up to date, and some new matter introduced. Abderhalden's protective ferments receive sufficient notice, and recent work on the Wassermann reaction has necessitated the re-writing of this section. Allusion is briefly made to more speculative work, such as the avoidance of anaphylactic shock by the production of anti-anaphylaxis, and the recognition of protection against diphtheria toxin by an allergic reaction. The treatment of the whole subject gains greatly in interest in this way. Dr. Simon primarily conceived his book for the enlightenment of the general practitioner. In its present form he believes that it may serve as a basis for a course of systematic instruction, and in this we agree with him.

*The Charaka Club.* Vol. IV. New York: William Wood and Co. 1916.—The fourth volume of the proceedings of the Charaka Club has much the same character as that of its predecessors, to which we have already made reference in these columns. The members of the club number some of the most prominent medical men who are practising or who have practised their profession in the United States; its object is to read papers and to promote discussion upon medico-historical subjects. There is no doubt that the interest of medical men in literary and artistic matters bearing on medicine has steadily increased of late, and to this agreeable fact it is quite likely that the publications of the Charaka Club have contributed, for the first two volumes are now out of print, and their messages must have been widely disseminated, though the membership of the club is small. The most important article in the present volume is a learned and fully illustrated dissertation upon Saint Cosmo and Saint Damien, the patron-saints of surgeons, apothecaries, and barbers, whose presentations confront us so frequently in the picture-galleries of Venice and Florence. Other interesting papers are one by Dr. Collins on the literary leanings of the physicians of the eighteenth century and one entitled "The Development of Anatomical Illustrations of the Nervous System," by Dr. C. L. Dana. Vesalius stands out among all the early illustrators of neurology for his knowledge and accuracy, but the diagrams made practically at the same time—i.e., 1545—by Charles Estienne (Stephanus) are wonderfully good, judging by the examples furnished by Dr. Dana. A sad history attaches to a sketch of the history of the University of Alexandria, as the author, Dr. J. G. Mumford, died just before its publication. A biographical note on Antonio Scarpa is supplied by Dr. A. G. Gerster. Dr. Pearce Bailey sends a short story of some medico-psychological interest, and the Bacon and Shakespeare controversy is reviewed from the botanical aspect by Dr. G. L. Walton.

*The Care of the School Child.* Edited by JAMES KERR, M.A., M.D.Cantab. London: The National League for Physical Education and Improvement. 1916. Pp. 230. Price 2s. 6d.—Bishop Boyd Carpenter introduces the reader to an admirable series of popular monographs, each by an expert, reprinted from lectures delivered under the auspices of the National League for Physical Education and Improvement during the summer months of 1916. The lectures are popular in the best sense; they may readily be understood by anyone who cares to read them with attention, but they contain the most recent knowledge on the subject in hand and the proper deductions from this knowledge. The chapters on malnutrition and the cripple child seem to us specially helpful. The book will be read with advantage by parents, teachers, nurses, health visitors, medical students, and even practitioners.

*Human Temperaments.* By CHARLES MERCIER, M.D. Lond., F.R.C.P.Lond. London: The Scientific Press, Limited. Pp. 91. Price 1s. net.—Dr. Mercier in this small book sets out the description of ten well-known types of character drawn from his personal study of men and women. He begins by amusing and adroit chapters defining temperament generally, cleverness, and capability, and proceeds to describe the artistic, religious, envious, jealous, and suspicious temperaments, the man of action the practical man, the man of

fads, the man of business, and the philosopher. The essays are written in Dr. Mercier's well-known style—they are witty, pithy, and dogmatic, and display a wide range of observation and learning. Thinking people must endorse a great many of Dr. Mercier's generalisations—a statement which is likely to tempt Dr. Mercier to modify them; but no one who presumes to have opinions of his own, and who possesses any experience with which to back them, is likely to agree completely with him, so that opportunities for battle are provided. We recommend the brochure cordially to our readers. It is always extremely readable and often very wise.

*Wheels: An Anthology of Verse.* Oxford: B. H. Blackwell. Pp. 84. Price 2s. 6d. net.—We are not often asked to express an opinion upon verse, and, when we are, the object of the writer has generally been the illustration by social incidents or pathological phenomena of some medical doctrine or moral. Such volumes are almost invariably failures, dull when they are serious and unspeakably so when they are in jocose vein. "Wheels" has no medical aspects whatever, save the unconscious revelation by the authors that the psychology of the cultivated youth of to-day finds ready and graceful expression in verse—where their fathers wrote short stories and their grandfathers long essays, they sing. The camps and the trenches during the past two years have produced many copies of verses having claim to notice as beautiful poetry, and "Wheels," though little of its contents may have been written in the circumstances of war, has an origin similar to that of the rapidly increasing war anthology. It is composed, speaking for its common and essential quality, of impressions suddenly seized and handed on by writers who are conscious of what has been suggested to themselves and who are determined to share the suggestion with others. The idea of these young poets is that the rôle of poetry is rather to crystallise fleeting views and aspects, to catch and fix vague and half-formed ideas, than to do any of the brave things associated in popular literature with the title of poet—to lead, to uplift, to amaze. The inspiration of these nine different writers—different in style, technique, and standard of accomplishment—has been a common one. They strive to show that any impression received by one person should be communicable to others by the medium of symbolic word-pictures; and, says the preface,

Our words are turned to spokes that thoughts may roll  
And form a jangling chain around the world  
(Itself a fabulous wheel controlled by Time  
Over the slow incline of centuries).

We recommend the book to lovers of verse, leaving them to decide which spoke of the wheel they prefer, and to guess which individual singer is most likely in the future to gain a large audience or make a stronger individual effort. The contributors are Edith, Osbert and Sacheverell Sitwell, E. Wyndham Tennant, Arnold James, Victor Perowne, Nancy Cunard, Helen Rootham, and Iris Tree.

*Poland's Case for Independence: A Series of Essays illustrating the Continuance of Her National Life.* London: George Allen and Unwin, Limited. Pp. 352. Price 7s. 6d. net.—The essays which make up this book have been supplied by the Polish National Committee and have been written to prove that the national life of Poland has never ceased to exist, despite the brutal fate which has been meted out to the country by the militarism of more powerful States. The book interprets the manifestation of that life to foreigners, and especially to the people of Great Britain, who have been persistently friendly to the Poles, and in our opinion the claim of the writers is made entirely good that a country which has manifested such indestructible vitality has a right to the independence she claims. The essays comprise one by Dr. R. W. Seaton Watson on the landmarks of Polish history and another by Mr. Rajmund Kucharski describing the persistent struggle for independence. Mr. Arthur E. Gurney contributes usefully on the population question, showing what were the extensive territories which up to 1772 constituted the Commonwealth of Poland and what were the nationalities of the various inhabitants. This chapter appropriately precedes an essay by Mr. Stanislaw Posner upon Poland as an independent economic unit; and the book closes with sketches of the history of intellectual Poland, its literature, art, and music. From the outset of the war it has been felt that the settlement of Poland will form a question of the utmost importance, and one whose adjustment requires a sympathetic knowledge of Polish affairs such as is here shown.

#### JOURNALS.

*Annals of Tropical Medicine and Parasitology,* Vol. X., No. 1.—This number of the annals contains four articles, three of which are contributed by Dr. J. W. Scott Macfie, of the West African Medical Staff, and pathologist to the colony of the Gold Coast, the fourth being furnished by Professor J. W. W. Stephens, of the University of Liverpool. Dr. Scott Macfie's first paper describes a fourth variety of trichonocardiasis affecting the shafts of the hairs in the axilla and groin, and caused by *Nocardia tenuis*, either alone or associated with a chromogenic organism. His second contribution is entitled "Observations on Urinary Amoebiasis," and in this he makes reference to three cases which were recently investigated in the Gold Coast, the infection in these instances, as well as in the few others already reported by previous observers, being due to *Entamoeba histolytica*. Urinary amoebiasis, it appears, may be due to a primary infection, or it may be secondary to amoebic dysentery. Cystitis, tumour of the bladder, and gonorrhœa are said to be predisposing causes. Dr. Scott Macfie's third contribution deals with the morphology of certain spirochaetes of man and other animals, and is illustrated by a number of drawings in the text. He describes a spirochæte which was found in the discharge from a mild case of vaginitis in a native woman, this organism being regarded as the causal agent of the disease. Another spirochæte was discovered inhabiting the bladder of a male patient suffering from chronic cystitis; while a third variety of spirochæte was found in the throat of a native affected by pharyngitis. Included in this paper are some interesting observations on the intestinal spirochaetes of certain of the lower animals, including the monkey, rat, sheep, cattle, goat and pig, in the faeces of which spirochaetes of the *S. eurygyrata* type were discovered. Professor Stephens's paper is a continuation of his previous "Studies in Black-water Fever," and in it he urges the importance of population statistics being supplied in connexion with reported cases of this disease. He points out that it is high time that the disputed questions regarding this malady were settled, and that systematic attempts should be made to obtain detailed information from official and other sources in localities affected by blackwater fever. The incompleteness of the statements sent by some observers often rendered their contributions entirely valueless. For the assistance and guidance of those who may in future compile local statistics of this disease, Professor Stephens puts forward several forms which can be filled up, giving all the information that is needed.

*British Journal of Ophthalmology.*—The appearance of the first number of this journal, the title-page of which is the epitaph of the Royal London Ophthalmic Hospital Reports, the *Ophthalmic Review*, and the *Ophthalmoscope*, marks the beginning of a new era in the literature of British ophthalmology. The journal is in the enviable position of being without a rival, a position which is not free from danger. Judging, however, by the first number and by the imposing list of names of the editorial committee, which includes ophthalmologists of all parts of the Empire, there would seem to be little fear of the journal succumbing from lack of driving power. The editor, Mr. Sydney Stephenson, founded the *Ophthalmoscope* and by his zeal and skill made it a great success. His long experience is a most valuable asset, and he is ably seconded by the assistant editor of the *Ophthalmic Review*, Mr. Erskine Henderson. After a few remarks on the origin of the journal, and the expression of a cordial welcome by American colleagues, the Nestor of English ophthalmology, Mr. Priestley Smith, leads off with a highly scientific communication on the Blood Pressure in the Eye and its Relation to the Chamber Pressure. We consider it a good omen that original research is thus early and emphatically recognised, and that the second place should be given to pathology in a paper on Choroidal Melanomata by Mr. Foster Moore. Then follow three papers on the removal of foreign bodies by the magnet, the most important of which, by Mr. M. H. Whiting and Mr. C. Goulden, records the experiences and lessons of war work in France. In the abstracts from ophthalmic literature the excellent method of collecting several papers on allied subjects for review is adopted. Book notices and notes on matters of current interest conclude the number. Of the 74 pages, 42 are devoted to original communications. The paper, printing, and numerous illustrations are all excellent. We wish our new contemporary every success.

# THE LANCET.

LONDON: SATURDAY, JANUARY 13, 1917.

## Preventive Treatment in Relation to Venereal Disease.

IN every infectious complaint there is a stage between infection and the appearance of evidence of disease, that symptomless incubation period which is still full of mystery in spite of our increasing knowledge of the life-history of disease germs. This period should logically be the most favourable time for treating disease or—if exception be taken to the word treatment in this connexion—for the preventive treatment of disease, reserving the word prevention for the avoidance of infection. Regarding the incubation period, then, as an ideal time for the application of measures of preventive treatment, the field of such treatment becomes a vast one if we only are aware in every case when infection actually takes place. In most instances, however, exposure to infection passes entirely unnoticed, or if noticed the chances of escape are so great, and the risk from disease itself so small, as to lead most people to neglect treatment even if available. Only in the case of dangerous and awe-inspiring plagues, such as small-pox and tetanus, is the demand for preventive treatment on the part of those who have been exposed to infection an urgent one, and it is well known how successful is the immediate vaccination or revaccination of small-pox contacts and the preventive inoculation with tetanus antitoxin of the victims of grievous wounds.

There is, however, a special case for preventive treatment. The possibility of infection with venereal disease must be present to the minds of all, excepting the most carelessly ignorant, of those who indulge in promiscuous sexual intercourse. A definite occasion for infection has been present which cannot be overlooked, and Sir BRYAN DONKIN's letter to the *Times* last week calls attention to the fact that it would be a fresh safeguard to the community as well as to the individual to antedate the treatment for venereal disease to the period of incubation, before the symptoms have had time to appear. Scientific research has, he says, shown conclusively that venereal infection can be prevented more surely than it can be cured by even the best methods of prompt treatment, and this fact was securely established by the precise experiments of the late Professor METCHNIKOFF. Sir BRYAN DONKIN's allusion is to the method of inunction of a calomel ointment as soon as possible after exposure to infection, described by METCHNIKOFF in his Harben lectures delivered in London ten years ago and translated from the French in our columns at the time. How far progress has been made since then is witnessed by the fact that in military administration, directed to the only organised group of society in which, before the awakening of to-day, measures had been adopted to deal with venereal

diseases, this inunction has already become a routine measure. An Army Order issued in March of last year directed medical officers to arrange an organised system by which soldiers who had exposed themselves to the danger of venereal infection were required to attend for treatment within 24 hours of infection. Men returning to barracks at any hour of the day or night were to have access to a room in the charge of an orderly who should superintend an efficient urethral irrigation with permanganate solution and an inunction into the glans penis of calomel ointment (calomel 33 parts, lanolin 100, vaseline 10). We understand that in the case of one battalion of 1700 men in which these facilities for preventive treatment were introduced the incidence of venereal disease immediately fell to less than a quarter of its previous figure.

The value of early preventive treatment, then, in the case of venereal disease is as well established as it is for small-pox and tetanus, and its wide application is equally indicated in the interests of individual and public health. Early preventive treatment must take its natural place in any well-considered scheme for control of venereal disease. It may well be that provision for the use of civilians of the facilities already provided for soldiers would result in a similar limitation of disease, and thus of the necessity for prolonged treatment. We are only concerned now to consider in any detail the medical aspect of the question, believing, as we do, that here as elsewhere physical and moral hygiene go hand in hand, and that it is impossible to develop one at the expense of the other. It has now come to be generally accepted that the provision of early and effective treatment of the diseases acquired by promiscuous sexual intercourse is not going to increase the incidence owing to the removal of moral restraint; but the idea of a Mikado-deity who must not be thwarted in his schemes for making the punishment fit the crime has died very reluctantly. The same mediæval doctrine has been applied during the lifetime of most of us to the treatment of the later stages and of the sequelæ of syphilis and gonorrhœa. Not only did some of our medical charities refuse, with the countenance of the regulations under which they were founded, to assist the victims of venereal disease, as far as they were able to diagnose such victims, but even the medical schemes organised by the public for mutual medical benefit—medical aid associations and sick clubs— withheld treatment from venereal sufferers. We have changed all that, and to-day the municipal schemes for the control of venereal diseases concern themselves keenly with the treatment of the earlier stages of those diseases. The application of the same doctrine to early preventive treatment is a logical step forward, and ought to be taken at once.

## Mobilisation of the Medical Profession.

THE subject of the mobilisation of the medical profession came before a special meeting of the Panel Committee for the County of London on

Tuesday last, when a report submitted by the Finance and General Purposes Subcommittee was considered in detail. The report recognised the urgent necessity of providing additional officers for the Royal Army Medical Corps, its authors being convinced by confidential information which had been submitted to them that a large number of additional practitioners would be required for military service.

The very important resolution recently passed by the Central Medical War Committee with regard to mobilisation approved, it may be recollect, of the principle of mobilisation of the medical profession apart from any question of general mobilisation of the community. For the Central Medical War Committee desire that every individual whose name is on the Medical Register shall be held bound to give such service as he is competent to give when required to do so by the State. On this broad question of the mobilisation of the medical profession as an individual entity the Panel Committee for the County of London have made no pronouncement, but they consider that if such a proposal were carried into effect it is essential that the arrangements for mobilisation should be under the control of a purely professional committee. They find that the Central Medical War Committee, strengthened in certain directions, would be the most suitable body to undertake the important work. The recommendations of the Panel Committee provide accordingly for the addition to the Central Medical War Committee of "at least six practitioners actively engaged in panel practice, one of whom should be a woman," and they consider, further, that without serious interference with the medical needs of the civilian population much greater use could be made in the future of the part-time services of civilian doctors. Civilian doctors could, they hold, be advantageously employed in the treatment of sick and wounded soldiers whilst in hospitals, as well as for the discharge of other military duties at home. We are certain that the members of the Panel Committee for the County of London are well aware of the difficulties attached to this proposal, but it is the expression of a very general feeling, and one which we share ourselves. We believe that in this way an economy of personnel could be effected and more medical men found to meet the demands of the Director-General of the Army Medical Service.

We regret the recommendation of the Panel Committee that the members whom they desire to see added to the Central Medical War Committee should necessarily be engaged in panel practice. The probability, of course, is that those selected for the purpose would be in active panel practice, but it is perilous to attach conditions which might become hampering. The views of those in panel practice can be fairly stated by anyone really familiar with the circumstances, and it is conceivable that panel practitioners might by restricting their representation to one of themselves be deprived of the offices of a particularly good nominee.

## Annotations.

"*Ne quid nimis.*"

### HEALTH OF THE PRISON POPULATION.

Few people regard the prison as a health resort, but the contention that such is the case in prisons in this country would be made plausible by a perusal of the report of the Commissioners of Prisons which we publish in another column. The average death-rate in local prisons for the last 25 years has been less than 0·5 per 1000 receptions, and although for the year under review it is nearly 50 per cent. greater, the increase is entirely explainable by the altered age groups of the prison population. Prisoners of military age naturally are healthier and contribute less to the prison death-rate than do the older malefactors, and the actual number of prisoners of military age received in prisons has diminished to less than one-third in the last three years and entirely out of proportion to the reduction in older prisoners. The death-rate from natural causes in convict prisons is, of course, much higher: 6 per 1000 of the daily average population during the last ten years and 8 per 1000 for the year under review. No emphasis can here be laid on slight fluctuations as the total convict population is so small—under 2000, in fact, at the end of the year. No epidemic of infectious disease occurred during the year, and only 13 scattered cases in all; 3 each of enteric fever and erysipelas, the remainder being ordinary infectious fevers of a mild type. A comparative picture of prison life under less healthy conditions may be gained from Lieutenant-Colonel W. J. Buchanan's report for 1915 on the jails of the Bengal Presidency which has just come into our hands, and the comparison is not an unfair one in respect of numbers as the daily average number of prisoners is not widely different: 11,311 under the care of the English Commissioners, and 14,494 in Bengal, bearing in mind, however, that of the first number only about one-fifth are convicts, while of the Bengalese 97 per cent. are convicts. There is the initial striking fact that the death-rate amongst the Bengal convicts during 1915 was over 20 per 1000, being nearly three times the rate among convicts in the prisons of England and Wales. Of the 264 deaths among Bengal convicts in 1915, 77 were due to dysentery, 24 to malaria, 18 to diarrhoea, in addition to 38 from tuberculosis and 26 from pneumonia. Lieutenant-Colonel Buchanan, whilst attributing this melancholy death-rate largely to the very serious overcrowding in the prisons, remarks that in the district jail of Barisal the persistent care and attention given by the medical officers has resulted in practically stamping out dysentery from this jail, but he goes on to record the very serious mortality in Dinajpur which blots the year's administration. In this jail of 315 inmates there is a daily average sickness of 29 and a death-rate of 119 per 1000, 18 deaths during the year being due to dysentery, 2 to malaria, 4 to pneumonia, and 2 to diarrhoea. In regard to this jail Lieutenant-Colonel Buchanan writes: "I have urgently pressed on Government the great need of a hospital here. This jail is one of the worst of the East Bengal jails, and the medical officer has not a fair chance in treating the sick drawn from an unhealthy district in the present old barrack wards used as a hospital."

The standard of mental health of the prison population is not a high one for a variety of reasons. The English Prison Commissioners report the number of persons in local prisons found to be insane after reception as 103 (126) and in convict prisons 36 (26), the numbers in brackets being those for the previous year. Of the cases certified in local prisons three-fourths were regarded as already insane on reception and another 7 showed symptoms of insanity within a month of reception. The war has had a remarkable effect upon the prison mental standard on account of the absence, already noted, from the prisons of strong able-bodied men. The Commissioners record their belief that the country's call for men has appealed as strongly to the criminal as to other classes, and it is a remarkable fact that receptions to prison are now principally confined to the mentally as well as physically weak. The Commissioners express their regret at the paralysing influence which the deficiency of State accommodation has exerted on the treatment of criminal defectives, but they look forward to the cessation of hostilities rendering possible an efficient administration of the Mental Deficiency Act. The present method of dealing with the confirmed and hopeless inebriate also comes up again for censure.

#### THE PIG AS A FOOD MIDDLEMAN.

THE Local Government Board and the Board of Agriculture and Fisheries are concerning themselves with the necessity for increasing the food productions of the country by the development of pig, poultry, and rabbit breeding. In regard to the two latter, few hygienic or dietetic problems arise. But the recommendation to increase the number of pigs, and that not only in rural districts, where space is abundant and neighbours are distant, raises very different questions. The hygienic aspect is at once apparent, and has led to the existence in a number of urban districts, as well as in a few rural ones, of by-laws prohibiting the keeping of pigs within a prescribed distance of dwelling-houses. We learn, however, from a recent circular of the Local Government Board that a regulation is about to be made enabling any local authority to give permission for the keeping of pigs either generally or in particular cases, notwithstanding by-laws to the contrary. To those acquainted with the habits of the pig under favourable surroundings this relaxation will not appear unreasonable. The pigsty often smells not because of the pig, but because of the ignorance of his keeper. Provided with a small area for the purpose the pig will dispose of his excreta without any nuisance whatever and with incidental enrichment of the soil, while his sty remains cleanly. It is the wholly confined pig who stinks. But on the dietetic side, in recommending pig culture as an economical pastime the fact must not be lost sight of that the alimentary canal of the pig is adapted for much the same kind of food as the human child's. The pig has no highly developed cæcum to deal with the conversion of cellulose into digestible carbohydrates. The growing pig is a typical omnivore and ordinarily receives a large amount of nutritive material, some of which the growing child could well digest. Experiments have shown that via the pig as middleman only some 25 per cent. of the protein and some 45 per cent. of the total energy value of the food supplied him is

ultimately returned to the consumer as pork or bacon. Brokerage of at least 55 per cent., which may well be largely exceeded, is charged by the pig. Pig culture can afford no excuse for wasteful housekeeping, and the presence in the pig-bucket of food which the family could have consumed is a disgrace to any patriotic housekeeper. The inspection of the amount of household waste might well become part of the sanitary inspector's routine duties at the present time. The case for pig keeping is more cogent where food refuse from hotels and institutions is in question. Food waste is apparently inseparable from civilised town life, and the pig may well be employed to redeem some of this waste if proper care is given to his lodging.

#### THE INTERNAL FORM OF HODGKIN'S DISEASE.

IN the *Journal of the Royal Army Medical Corps* Lieutenant T. H. Whittington has reported a case of the "internal" form of Hodgkin's disease of acute onset with relapsing pyrexia and signs and symptoms chiefly abdominal, which was very difficult of diagnosis and deceived the "very elect." A private, aged 19 years, was admitted to a base hospital from the trenches in Flanders on Nov. 21st, 1915. He looked pale and complained of pains in the soles, but nothing abnormal was seen in the feet. On the 24th the abdomen was distended, slightly tender all over, and rather rigid. The temperature ranged from 103° to 104° F.; the tongue was dry and brown. A leucocyte count showed a leucopenia of 3500. On the 27th he was sent to a hospital for infectious diseases as probably a case of enteric fever, and came under Lieutenant Whittington's care. He was very pale, with a rather "renal" appearance, and complained of headache. There was occasional muttering delirium with picking at the bedclothes. The pulse was very soft and occasionally dicrotic. There was marked tenderness with dullness on percussion in the left hypochondrium and left lumbar regions. This dullness appeared to be splenic, reaching down four finger-breadths below the umbilicus, but the spleen was not felt. The stools were fluid and yellow. No enlarged glands were felt. The serum reactions for the typhoid and paratyphoid bacilli were negative. The diagnoses so far suggested were acute peritonitis, recurrent appendicitis, and typhoid fever, the last being favoured. During the next week the abdominal distension diminished, enabling a firm and slightly tender spleen to be felt. The haemoglobin was only 52 per cent. From Dec. 2nd to 5th the temperature fell and the patient rapidly improved. On the 31st he again became listless and pale, and complained of pains in the soles and toes. The temperature again rose and the spleen rapidly enlarged. The temperature soon fell, only to rise again on Jan. 4th, 1916, when the spleen was still more enlarged and the liver slightly so. Blood examination showed 3000 white and 3,600,000 red cells per c.m.m. A differential count gave polymorphonuclears 80 per cent., lymphocytes 15, and large mononuclears 5. Several consultants saw the patient, and the diagnoses suggested were: a typhoid relapse, splenic anaemia, and tuberculous peritonitis, but Hodgkin's disease, Malta fever, kala-azar, congenital syphilis, and septicaemia were also discussed. He again improved, but another relapse followed, the abdomen being distended and showing free fluid in the flanks. There appeared to be an indefinite mass above the umbilicus. He became very emaciated and jaundiced,

and died on Feb. 15th, 12 weeks after the onset. At the necropsy much yellowish fluid was found in the abdomen. The spleen was thrice the normal size and hard and showed on its surface and on section yellowish-white spots. An enlarged gland in the portal fissure seemed to press on the hepatic duct. The retroperitoneal glands formed a large, irregularly lobulated, hard mass. Some enlarged glands were found below and behind the inner ends of the clavicles. Microscopic examination showed the typical appearance of Hodgkin's disease. In McNalty's study of "Lymphadenoma with Relapsing Pyrexia,"<sup>1</sup> 8 cases out of 32 are described as without enlargement of the superficial glands. In only 2 of these was the duration shorter than in the present case. In a man, aged 23 years, the mediastinal glands, spleen, liver, and kidneys were affected and he died after five weeks. In the other the mesenteric and bronchial glands, liver, and spleen were affected, and death occurred after seven weeks. The other patients lived for periods varying from 4 to 15 months.

#### THE PARLIAMENTARY REPRESENTATION OF DUBLIN UNIVERSITY.

WE published last week a letter from the Professor of Anatomy and the Professor of the Practice of Medicine in Dublin University, urging upon those of our readers who are entitled to vote for the Parliamentary representation of the University to record their support at the forthcoming election in favour of Sir Robert Woods, M.D. Dub., who is standing as a non-party candidate. Sir Robert Woods approaches the electors with the plea that he is the representative of the medical faculty of the University, which is notoriously one of the most distinguished faculties, while Mr. Arthur W. Samuels belongs to the profession of law which, except in one solitary instance, has for half a century supplied the constituency with its Parliamentary member. The issue, in fact, is one to be decided between the profession of medicine and the profession of law, for both candidates disclaim party views in politics. Mr. Samuels describes himself as "a Unionist and Imperialist," with no reference to party interests. Sir Robert Woods is equally detached. In answer to a correspondent he has written: "I shall resist with all my power any attempt to revive the Irish controversy during the period of the war ..... and to coerce any section of the Irish people into a settlement which it does not desire. If, however, with the full and free consent of the Unionists of Ulster and the Unionist minority of Dublin and the South of Ireland, and with the full sanction of the Imperial Parliament, a real settlement of the Irish question is evolved, after the war, by the united statesmanship of both countries, I shall do my best to help it in every way." We wish Sir Robert Woods every success, because it is constantly brought home to us that the presence of more medical men in the House of Commons would be of great value to the country. The ignorance displayed by the majority of Members of Parliament upon all medical points is illustrated by the nature of the questions in the House of Commons no less than by the way in which medical, and indeed all scientific, interests are too often sacrificed to the interests of other sections of the community. At the Conference of Educational Associations held at the University of London last week Sir Alfred Keogh said it was a regrettable thing to find Cabinet Ministers,

prominent administrators, and other people in high positions having no knowledge whatever of the elementary facts of science. He had to place scientific questions before these men, and he found it difficult to get low enough to reach their level. Every medical Member of Parliament helps to improve the situation, and from this point of view alone Sir Robert Woods may fairly expect votes.

#### OSTEOCHONDROMATOSIS OF JOINT CAPSULES.

IN 1900 Reichel published the first description of a rare condition characterised by the appearance of multiple osteochondromas in the capsules of one or more of the joints. Dr. J. W. Kopp<sup>1</sup> has recently recorded three new instances of this complaint, affecting the knee-joints in each patient, and he has found 11 others in medical literature. In 10 of the total of 14 patients the knees were involved; the ankle, wrist, elbow, hip, and metacarpophalangeal joint of the middle finger have also been found affected, each in different cases. In three patients, including one of Dr. Kopp's, both knee-joints were diseased; otherwise the osteochondromatosis has apparently been confined to a single articulation. The disease may occur at any age, and although the new growths show no sign of malignancy they may recur after their operative removal, by arthrectomy or resection of the joint, has been attempted. This, no doubt, is a consequence of incomplete removal. In Reichel's case the patient was a man of 36 with a very chronic and almost painless affection of the knee. The joint was opened and a quantity of blood was removed from its cavity, together with two handfuls of loose cartilaginous fragments. Recovery followed; shortly afterwards Reichel opened the joint again and removed a number of loose, bluish-white cartilaginous fragments, but an attempt to dissect out the whole capsule of the joint, which was beset with numerous cartilaginous nodules of various sizes, was baffled by the discovery of similar nodules on the cruciate ligaments. Resection showed that the articular surfaces of the femur, tibia, and patella were unaffected, and that the new growths originated in the capsule of the joint. Dr. Kopp's first patient was a healthy student, aged 24, who came under observation in 1911 with a history of slight pains in the right knee for four years. The condition was attributed to trauma of an unusual character to which the attention of neurologists may be drawn—percussion of the patella with a percussor in a wanton moment during a joyous evening. The patient's gait was normal, but there were symptoms of the nipping of a foreign body in the joint. The joint itself showed an unsymmetrical swelling of the synovial membrane and the suprapatellar bursa, with fluctuation and limitation of movement to about 75°. Numerous free foreign bodies could be felt in it, and one, the size of a grape, lying on the inner side of the patella, could be moved two inches in any direction, but always returned to the same place, whence it was concluded that it had a peduncle. All the other joints seemed normal. This patient had had comparatively little trouble with his knee when he was seen again in 1914, and he refused operation; skiagrams were taken and are reproduced by Dr. Kopp in his paper. They show a curious dappling of most of the area subtended by the synovial membrane, but no changes in the structure of the bone or their articular surfaces. Dr. Kopp's second patient, a man of 39, gave a history of slight

<sup>1</sup> Quarterly Journal of Medicine, October, 1911.

<sup>1</sup> Nederl. Tijdschr. v. Geneeskunde, Amsterdam, 1916, II., 1175.

trauma of the knee some 15 years before. Three years later he had had symptoms pointing to the nipping of a loose body in the joint. Dr. Kopp found swelling of the joint and suprapatellar bursa, and in both could be felt some movable and hard foreign bodies. The joint was opened under ether anaesthesia, and an incomplete arthrectomy was performed. Two free foreign bodies were found in the prepatellar bursa. The outer surface of the synovial membrane was found to be studded with bluish-white opalescent nodules, the largest as big as a pea. There was no evidence of inflammation and the synovial fluid was clear. Careful examination showed that these nodules arose from the synovial membrane only, and not from bone, cartilage, ligament, or muscle. The ends of the bones exhibited the appearances of arthritis deformans in its early stages. The patient made a good recovery from the operation, and was well satisfied with its results when he was seen again 20 months later. But a couple of foreign bodies could then be felt in the immediate vicinity of the right knee-joint, and Dr. Kopp concludes that it also was becoming affected with osteochondromatosis. The third patient was an old woman of 77 with senile dementia, who had foreign bodies in both knee-joints. Operation was not contemplated, but Dr. Kopp decided from the physical signs and skiagrams that he had here to do with a third case of this rare disease. Discussing its general diagnosis, he says that it has to be distinguished from osteoarthritis localised in some diverticulum of the joint, from the intra-articular exostosis cartilaginea first described by Volkmann in 1855, from arthritis deformans, and from the osteoarthropathies met with in tabes dorsalis and syringomyelia. As another possible source of confusion he mentions the fabella, a sesamoid bone appearing not rarely in the external head of the gastrocnemius. The pathogenesis of osteochondromatosis is uncertain. Reichel attributed it to infection; Lexer (1907) refers it to a developmental defect in the differentiation of the mesenchyma of the joint, comparable to that resulting in the growth of enchondromas about the bones of the fingers and toes. Dr. Kopp agrees with Lexer. The neoplasms removed from his second case were examined for him by Dr. de Josselin de Jong, who states that in this instance the nodules began life as minute osteomas in the capsule of the joint, and ended up as foreign bodies free in the joint, where they became covered with connective tissue and cartilage, while their bony core might develop into a calcareous mass. As for the treatment indicated, Dr. Kopp believes that recurrence is likely to follow arthrectomy or excision of the capsule of the joint, and that nothing short of resection of the whole joint will give a permanent cure.

#### SANITATION AND DISEASE IN BENGAL.

THE work of combating disease in India is rendered difficult by the indifference of the people to elementary hygienic precautions. The annual report for 1915 recently issued by the Sanitary Commissioner of Bengal illustrates this fact in a striking manner. The ravages of cholera in the Presidency during the year were very great, the number of deaths due to that disease being over 130,000, an increase of 41,000 on the total of 1914. The districts which suffered most severely were Mymensingh and Malda, and the high rate recorded is explained by the action of the people themselves. Dealing with Mymensingh, the civil surgeon writes: "In August, when a large part of the district was

under water, dead bodies of cholera patients were, in two subdivisions of the district, thrown into the flood water, which spread the disease far and wide till the end of the year. These two subdivisions were responsible for 18,819 deaths out of a total of 26,662 in the whole district." This record is supplemented by the account given by the civil surgeon of what occurred in Malda. "From some of the bordering villages dead bodies were thrown into the river, and this contaminated the water and facilitated the spread of the disease to the villages situated on it." It is not surprising, in view of the facts we have cited, that the Sanitary Commissioner should declare that outbreaks of cholera must be counted as annual events so long as the majority of the sources of water-supply remain subject to gross contamination. But even where waterworks are installed and a pure supply is forthcoming the advantages thus afforded are not universally appreciated. Thus, at Berhampore, which has been provided with a pipe-supply, certain classes of the inhabitants persisted in drinking unfiltered water brought from the river, with the result that 74 deaths from cholera took place among them last year, while those who availed themselves of pipe-water remained immune to the disease. Bengal occupies the unhappy position of being the only part of India where the death-rate exceeded the birth-rate in 1915. The increase in mortality was largely due to cholera and small-pox, while the diminution in the birth-rate is ascribed to the deficiency in rainfall in 1914, which by preventing a decline in the prices of food grains affected the vitality of the poorer classes. The Government resolution on the Sanitary Commissioner's report expresses the opinion that the best prospect of permanent improvement in village sanitation lies in the widespread formation of union committees and the free exercise of their powers of local taxation. The Governor agrees with the Commissioner that much immediate improvement, which would also have an educative value, could be attained through the personal interest and initiative of district officials.

THE death is announced, at the age of 90, of Jean Baptiste Auguste Chauveau, professor of comparative pathology in the Paris Natural History Museum, and one of the most famous physiologists of his time.

A MEETING of the British Hospitals Association will be held at St. Bartholomew's Hospital, London, on Friday, Jan. 26th, at 3.30 P.M., when a paper will be read by Dr. W. J. Howarth, medical officer of health for the City of London, on the Treatment and Control of Venereal Diseases, with Special Reference to the Voluntary Hospitals. At the close of the proceedings the annual meeting of the association will be held to appoint officers for the ensuing year.

THE Royal Institute of Public Health has arranged an admirable series of public lectures on health problems under war and after-war conditions to be delivered every Wednesday afternoon at 4 P.M. from Jan. 17th to March 28th inclusive in the lecture room of the Institute at 37, Russell-square. Medical officers of health, medical practitioners, and all those engaged in public health and national services are invited to attend. The first lecture, on Wednesday next, will be delivered by Dr. Janet Lane-Claypon on Child Welfare Work, with Sir Robert Morant in the chair. Due notice of the other lectures will be given in the Diary.

**THE LANCET, VOL. II., 1916 :  
THE INDEX.**

THE Index and Title-page to the volume of THE LANCET completed with the issue of Dec. 30th will be ready on Jan. 22nd. Owing to the continued shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a post-card to the Manager, THE LANCET Office, 423, Strand, London, W.C., when a copy of the Index and Title-page will be supplied free of charge.

**PRISON COMMISSIONERS' REPORT.**

THE report of the Commissioners of Prisons and the Directors of Convict Prisons for the year ended March 31st, 1916, which has been presented to Parliament, does not contain the usual report of the Medical Commissioners. This report, along with those of the visiting chaplain and surveyor, having been omitted on the recommendation of the Committee on Public Retrenchment. A number of paragraphs in the report itself, however, deal with medical topics.

*Medical Matters Dealt with in the Report.*

The death-rate in local prisons from natural causes was 0·77 per 1000 prisoners received, the average for the previous 25 years having been 0·49 per 1000. The death-rate from natural causes in convict prisons was 8·2 per 1000 of the daily average population, as compared with 6·1 for the past ten years. But this apparent rise in death-rate must be brought into relation with the great alteration in the age-groups of the prison population. An earlier paragraph explains the alteration thus:—

The enlistment of many habitual petty offenders of military age can be inferred from the fact that for the year ended March 31st, 1914, the percentage of male prisoners of the age categories over 40 received on conviction formed 40 per cent. of the total population. For the year ended March 31st, 1916, this percentage had risen to 49, while the actual number of prisoners received of military age had fallen from 61,739 to 19,169 during these years.

The number of persons in local prisons found to be insane and certified as such after reception was 103, as compared with 126 last year, and in convict prisons 36, as compared with 26. Of the 103 cases certified in local prisons, 76 were found to be insane on reception and 7 exhibited symptoms of insanity within a month of reception. Many of those who were in prison for some time before the usual symptoms of insanity were observed were known to be of weak intellect or mentally impaired on reception, or to have been previously insane. As with the death-rate so with the incidence of insanity, the figures do not reflect the normal results of prison life.

The war has again had a marked effect on the average mental condition of the prison population, an effect which is described in the following interesting paragraph:—

One of the notable effects of the war on the prison population has been that the receptions are now for the most part confined to the physically and mentally weak. The general standard of physique is now much inferior to that of prisoners admitted into prison in normal times, while the percentage of strong able-bodied men is comparatively small. There is every reason to believe that the country's call for men appealed as strongly to the criminal as to other classes, and if it had been possible to place under scrutiny every case admitted into prison within military age, there is little doubt but that the vast majority of cases would have been found to be physically unfit. A young burglar, one of a gang of five, told the chaplain of a London prison that his four pals had enlisted; two had been killed and two others wounded. He said he meant to go and "do his bit" as soon as he got out of prison—a promise which he faithfully observed.

The number of prisoners who were released from local prisons on medical grounds, exclusive of pregnancy, &c., but including 8 cases temporarily released under Section 17 (6) of the Criminal Justice Administration Act, 1914, was 31 and from convict prisons 2. There were 4 suicides in local

prisons during the year and none in convict prisons. The daily average number of prisoners in hospital in local prisons was 361—225 males and 136 females—this being a proportion to the general prison population of 3·5 and 7·3 per cent. respectively. Thirteen cases of infectious disease were reported during the year—enteric fever, 3; erysipelas, 3; measles, 4; scarlet fever, 2; mumps, 1—as compared with 11 cases last year—viz., enteric fever, 1; chicken-pox, 2; scarlet fever, 2; diphtheria, 2; mumps, 1; and erysipelas, 3.

*Mental Deficiency Act.—Convictions for Drunkenness.*

As in the last year's report, allusion is again made to the difficulties which have arisen, owing to the outbreak of war and other causes, in the exercise of the Mental Deficiency Act so far as it relates to inmates of penal institutions. The Commissioners regard the record for the year under report as not an encouraging one. During the year 204 prisoners—130 males and 74 females—were certified under Section 1 of the Mental Deficiency Act, as compared with 248 last year. A large number of the 248 certified during 1914–15 have been received again, many several times, on re-conviction. Orders were made by the Secretary of State, under Section 9 of the Act, in 39 cases—10 males and 29 females—and these were removed to certified institutions, or, in the case of some of the females, to the Farmfield State Institution. In addition 26 males and 22 females were handed over to local authorities on discharge. The absence of institutional accommodation for defectives, and particularly State accommodation for males, exercises, in the Commissioners' view, a paralysing influence on operations under the Act as regards the disposal of criminal defectives. But a more hopeful note is struck for the future.

On the vexed question of the alleged increases of drunkenness among women much fresh light is thrown by an inquiry made by the Lady Inspector of Prisons into the character of the population committed for drunkenness to Holloway Prison.

The inquiry showed that during the three years 1913, 1914, and 1915, 10,888 committals on conviction of drunkenness were recorded against 1628 women, who, including the convictions incurred in years preceding 1913, had on their combined records a total of 30,986 convictions. Of these 1628 individual prisoners—

1092	were received in 1913, incurring that year	2768	convictions.
1045	" " 1914	3931	"
813	" " 1915	4189	"

The average convictions, therefore, per individual rose from 2·6 in the year 1913 to slightly over 5 in 1915. Amongst the 1628 women was selected a group of 25, who, at the end of 1915, had each received ten or more convictions for this offence. All are stated to have been first offenders in 1913 or 1914. By the end of 1915 they had amassed a total of 353 convictions—viz., 69 in 1913, 134 in 1914, and 150 in 1915. As regards first offenders in the drunkard class, the totals received in each year were 113, 113, and 37 respectively.

The inquiry at Holloway thus substantiated the observations of several governors and chaplains at other prisons—viz., that a falling population is at the present time contributing more convictions per annum than was the case before the war. If the average rate of convictions per annum incurred by each individual at Holloway Prison for the years 1913–14 and 1915–16 respectively be applied to the total receptions on convictions of drunkenness for the whole country, a result is arrived at which shows an actual falling-off of about two-thirds in the numbers received for this offence.

In connexion with this increased rate of convictions for drunkenness per individual the Commissioners comment on the curious fact that there should have been a great fall in the number of habitual drunkards committed to inebriate reformatories. So far as the metropolis is concerned, the numbers fell from 95 in 1913 to 9 in 1915. This is due in part to the war; but the failure of the Inebriates Act, 1898, to deal with the problem of habitual alcoholism must now, in the Commissioners' view, be admitted. The Commissioners sum up the matter thus: "If medical observation shows that mental causes enter into the history of the confirmed and hopeless inebriate, the Mental Deficiency Act now provides the opportunities for dealing otherwise with the repeated offence of drunkenness than by the useless, and, we might say, senseless, methods hitherto prevailing of repeated sentence to short terms of ordinary imprisonment. This affords no cure—perhaps only an encouragement. It is unscientific in principle, and further degrades the subject—man or woman."

## KING EDWARD'S HOSPITAL FUND FOR LONDON.

A MEETING of the Governors and General Council of King Edward's Hospital Fund for London for the purpose of awarding grants to the hospitals, convalescent homes, and consumption sanatoria for 1916 was held on Dec. 15th at St. James's Palace, London.

Lord IVEAGH, who presided, read a letter from the King congratulating the Council of the Fund on the distribution of £170,000 this year, £30,000 more than last year's total, and £12,500 over the previous record achieved in the years just before the war. His Majesty also expressed the hope that the public would help to maintain this record.

Lord REVELSTOKE (the honorary treasurer) reported that the net receipts for the year to Dec. 11th, apart from receipts on capital account, had amounted to £269,526 18s. 6d. This included £100,000 cash received from Sir Walter Trower in respect of the residue of the estate of the late Isabella Countess of Wilton, and the Fund had already had transferred to it securities amounting to over £22,000. The Finance Committee were retaining the cash uninvested, so as not to hamper the discretion of the Council in deciding as to the use of the money in the event of any emergency.

Sir WILLIAM COLLINS, on behalf of the League of Mercy, said there was hardly any reason to doubt that the League would be in a position to make for the fourth year in succession a grant of at least £14,000 to the King Edward's Hospital Fund, and also to make a distribution of something like £3000 in the extra-metropolitan district.

Sir WILLIAM CHURCH (the chairman of the Distribution Committee) presented a report which stated that the sum available for distribution amongst the London hospitals was £162,500, as against £133,500 in 1915. This was the largest sum that has ever been distributed by the Fund amongst the hospitals, being an increase of £29,000 over the last two years, and £11,500 over the previous maximum of £151,000 which was reached in the years immediately preceding the war. The increase in grants in aid of maintenance was £28,075, and became possible because of the postponement of building schemes and the reduction of grants towards capital expenditure. Of the capital grants of £19,075 recommended this year, only £6525 was on account of schemes begun since the outbreak of war on the ground of exceptional urgency; the balance had been devoted to relieving hospitals of capital liabilities incurred before the war. They had as far as possible distributed the increased grants in proportion to the probable urgency of need in 1916, and had given rather greater weight than usual to the more permanent elements which affected a hospital's power to stand increased financial strain, such as the relative amount of fixed income and the relative amount of available reserve funds; but the actual results of 1916 could not be taken into account until the next distribution. The number of hospitals applying for grants was 107, being three in excess of last year. The committee, Sir William Church continued, received yearly evidence of the increasing work done by the voluntary hospitals in the cure or prevention of disease in co-operation with State or municipal authorities, apart from the treatment of naval and military patients. This was one of the numerous ways in which the hospitals took their part in promoting public health. The latest development in this direction was the preparation by various hospitals of schemes for the treatment of venereal diseases in co-operation with the Local Government Board and the London County Council in accordance with the recommendations of the recent Royal Commission. In one case, that of the London Lock Hospital, an application for a capital grant in aid of sanitary and other improvements at the female hospital had been received, and in view of the importance of increasing the efficiency of this hospital in these respects the committee recommended a substantial grant towards the sanitary improvements. The committee further recommended that the Council, which had already by large grants enabled the Male Lock Hospital to be brought thoroughly up to date, should also offer substantial assistance towards an approved scheme for the reconstruction of the Female Lock Hospital.

Mr. F. M. FRY then presented the list of awards which has already been published in the press. The largest individual

grant, £15,000, has been given to the London Hospital, while Guy's Hospital follows with £9000. The smallest grants (£25) go to some of the cottage hospitals.

Dr. EDWIN FRESHFIELD (the chairman of the Convalescent Homes Committee) presented a report stating that the sum available for distribution amongst convalescent homes and consumption sanatoria was £7500, as against £6500 in 1915, the largest sum that had ever been placed at the disposal of the Convalescent Homes Committee. The number of applications eligible for consideration amounted to 42 from convalescent homes and 9 from consumption sanatoria, as against 41 and 9 respectively last year. The committee had made a slight increase this year in the number of beds reserved at consumption sanatoria for the use of patients in London hospitals, owing to the fact that certain women's beds no longer available had been replaced by children's beds. The accommodation thus secured amounted to 53 beds at six sanatoria.

The list of grants recommended by the Convalescent Homes Committee having been presented by Mr. J. G. GRIFFITHS,

Lord IVEAGH, in moving the adoption of the report and awards, said it was with great satisfaction that they found themselves able to make a record distribution, and this apart from supplementary grants rendered possible by the generosity of Sir Ernest Cassel. It was one of the functions of the Fund to serve as a steady influence on the finances of the hospitals. The amount which the hospitals would get from the Fund in grants to maintenance, even in this record year, was only a little more than one-ninth of the total ordinary expenditure; while the very large increase in the maintenance grants would not cover the increase in their ordinary expenditure since the war began, reckoning only the year 1915. There was no doubt, moreover, that the need of the hospitals would continue to grow in the near future. The burden of 1916 would inevitably be greater, and if the Fund was to continue to do its part an increased distribution might become desirable. He wished to express the indebtedness of the Fund for the legacies of £20,000 received, under the will of the late Lady Brownlow, on the death of Sir Charles Brownlow, and £10,000 very kindly allocated to the Fund by the executors of the late Thomas Stephen Whitaker in the exercise of their discretionary power.

The Duke of NORFOLK having seconded the motion, the adoption of the reports was carried unanimously.

A meeting of the General Council of King Edward's Hospital Fund for London was held on Monday afternoon, Jan. 8th, at the offices of the Fund, 7, Walbrook, E.C. There were present the Speaker of the House of Commons (the Right Hon. James W. Lowther, M.P.), in the chair; the Earl of Beesborough; the Viscount Knutsford; Lord Burnham; Lord Somerlayton (honorary secretary); the President of the Royal College of Physicians (Dr. Frederick Taylor); the Right Hon. C. Stuart-Wortley, K.C., M.P.; Sir William S. Church, Bart.; Sir Owen Philips, M.P.; Sir Horace Marshall; Mr. Frederick M. Fry (honorary secretary); Mr. John G. Griffiths (honorary secretary); Mr. Robert Fleming; Dr. Edwin Freshfield; Mr. W. J. H. Whittall. The appointments were announced of Mr. W. J. H. Whittall to the General Council and of Sir Edward Hope, K.C.B., to the Executive Committee. The resolutions providing for the work of the Fund for 1917, which were approved at the meeting of the Governors and General Council, were formally adopted.

## MEDICINE AND THE LAW.

### *Humphreys v. Miller, Rendell, and Harbord.*

In this case, as will be remembered, it was shown that a lodging-house keeper let rooms to Mr. H. C. Miller, who resided there with his daughter until his death from leprosy, being attended in his last illness by Mr. E. A. Harbord. The plaintiff afterwards brought an action, tried by Mr. Justice Darling with a special jury, claiming damages against the executor of the deceased, his daughter, and Mr. Harbord, on the ground that there was an implied warranty when the rooms were taken that Mr. Miller was not suffering from any disease which would make it unfit or dangerous for him to occupy them or would prevent them from being in future let as furnished rooms; that Miss Miller knew that her father was not a fit person to occupy the rooms; and

that the father, the daughter, and Mr. Harbord concealed the fact from the plaintiff, in consequence of which the rooms were let. After a great deal of evidence had been given the jury returned answers in the plaintiff's favour to all the questions put to them, finding as facts that Mr. Miller when he took the rooms was liable to infect persons and furniture with leprosy, and that he and his daughter knew it; that the disease was communicable by infection or contagion in England; that Miss Miller and Mr. Harbord fraudulently misrepresented Mr. Miller as fit to occupy the rooms; that they concealed from the plaintiff that Mr. Miller was suffering from a disease which made him unfit and dangerous to occupy the rooms; that Mr. Harbord, acting as agent for the other two, stated that Mr. Miller was not suffering from any contagious or infectious disease, and that this was untrue, as he and Miss Miller knew; that all three conspired to conceal the state of Mr. Miller from the plaintiff, and made false statements with that object. Damages to the extent of £250 were awarded. Counsel for Mr. Harbord asked for judgment for his client *non obstante veredicto*, on the ground that there was no obligation upon him to disclose his patient's condition to the plaintiff and no evidence that he did not believe that in this country leprosy was neither infectious nor contagious. After further argument to the effect that there was no evidence to support the jury's findings, Mr. Justice Darling gave judgment for the defendants.

The Court of Appeal has since affirmed the decision of Mr. Justice Darling. Lord Justice Swinfen Eady held that there is no foundation in law for the argument that there is a warranty or condition that when a person takes furnished rooms he shall not be suffering from any disease which may be infectious or contagious; that there was no evidence that Miss Miller knew that her father was suffering from leprosy or from any infectious or contagious disease. With regard to Mr. Harbord, the evidence showed that he had nothing to do with the original taking of the rooms; he had told the landlady, when questioned by her, that the deceased was not suffering from an infectious disease, but had warned her to be careful, and that no one else was to use the lavatory used by the patient. According to the evidence, the risk of infection with leprosy in this country was practically *nil*, and that was Mr. Harbord's view. He honestly expressed the opinion that he held, and was under no obligation to divulge to the lodging-house keeper anything with regard to his patient. Moreover, the plaintiff could have determined the tenancy by giving a week's notice to her tenants. His lordship held that in view of the above Mr. Justice Darling was right in holding that there was no evidence upon which to base any finding which involved either of the defendants in liability to the plaintiff. Lord Justice Bankes, in concurring, said: "I see no evidence whatever on which it can be suggested as against this medical man that he did not honestly believe that, speaking practically, there was no danger either of infection or contagion from this particular disease." The appeal was therefore dismissed. That this case should have ended as it did, and that Mr. Justice Darling's judgment should have been upheld is eminently satisfactory, and the medical profession as well as Mr. Harbord is to be congratulated upon the result arrived at. The charge made in claiming damages was a charge of deliberate falsehood and conspiracy involving known danger to the health of innocent people for the convenience and in the interest of the medical man's patient. It is established that of all this there was no evidence. The fact that a case of leprosy was involved with the exposition of medical opinion as to this disease added incidental interest to the trial.

#### *Coroners' Juries in War Time.*

Three sane and useful suggestions have been made by Mr. S. Ingleby Oddie in a letter to the *Times* for economising money and men's time in connexion with inquests. He recommends that the coroner should be enabled by an Act of Parliament (1) to hold inquests without a jury, or (2) to hold them with a jury of seven, or (3) to order post-mortem examinations before deciding that an inquest is to be held. Of these it will probably be agreed by many that the adoption of numbers (1) and (3) not alternatively but simultaneously would be a useful innovation, and if such adoption were to be for the period of the war only, would constitute an experiment which need not be continued if it should prove unsuccessful. The third suggestion deals with a recommendation often made by coroners, which found strong support

at the hands of the Departmental Committee on Coroners' Law in 1910. The first should be favourably considered by those who remember that many coroners are, and all might be, medical men with sufficient legal training for the performance of a coroner's duties so far as they entail knowledge of law. It may be pointed out that the economy of money, time, and man-power effected would be on a more important scale than that involved in the recent abolition of reports of certifying surgeons on accidents, which had a similar object in view. Also it would not involve injustice to anyone whose functions would be dispensed with, or any loss of protection to the persons on whose behalf they are now exercised.

#### *The Slingsby Case.*

In this case a declaration was claimed under the Legitimacy Declaration Act, 1858, with regard to the alleged child of Commander C. H. R. Slingsby. It will be remembered that Mr. Justice Bargrave Deane found that the child was borne by Mrs. Slingsby at San Francisco, the allegation on the other side being that he had been procured for her from another woman. The Court of Appeal held that the evidence did not justify the finding of Mr. Justice Bargrave Deane, and the appeal on behalf of the child to the House of Lords has now been dismissed. A curious feature of the case consisted in the calling in of Sir George Frampton, the well-known sculptor, to express an opinion upon the question of physical resemblance on the part of the child to the parents who claimed him as theirs. Sir George Frampton was of the opinion that a strong likeness existed, and the judge appears to have thought so too. As to this Lord Loreburn, in the House of Lords, expressed the opinion that Mr. Justice Bargrave Deane's views of the evidence must have unconsciously been influenced by Sir George Frampton, while Lord Sumner said that any weight that might be attached to likeness was overborne by other evidence.

## PUBLIC HEALTH OF MANCHESTER.

IN his recently published annual report Dr. James Niven gives an instructive account of the health of the city of Manchester in the year 1915, and of the various preventive measures carried out under his direction, special reference being made to the administrative action taken locally for the control of tuberculosis. The appearance of this volume shortly after the issue of Dr. W. H. Hamer's report<sup>1</sup> for the same period affords opportunity for comparing the statistical records and sanitary defences of a well-equipped provincial city with corresponding data for the metropolis.

The "recorded death-rate" of Manchester was equal to 16.31 per 1000 at all ages, or 1.42 below the decennial average rate. The tabular records submitted are less complete than previously, and there is great doubt as to the total population of the city. Owing to the large number of enlistments, the age constitution of the civil population has seriously changed. Nor is this change confined to the male sex, since recent alterations of occupation have affected the distribution of women also. Either for reasons of economy, in war time, or else because of uncertainty attaching to population estimates, many of the usual tables are omitted in this report. But this omission has to some extent been compensated for by the Registrar-General, who publishes detailed periodical returns of mortality and of disease notification in each of the great British towns.<sup>2</sup>

The national records deal with the entire areas of the several towns, but in the present report essential particulars are given for each of the statistical divisions of the city. From these we learn that, as compared with the decennial average, the crude death-rate in 1915 shows a marked improvement in North Manchester and a considerable improvement in South Manchester, but a falling off in the old Manchester township. This supports the conclusion previously reached, that the poorer classes have suffered disproportionately in the last two years. Nevertheless, the average position of the Manchester working classes is believed to have improved, and there has been less pauperism in 1915 than in the two preceding years. In order to avoid

<sup>1</sup> THE LANCET, 1916, II., 837.

<sup>2</sup> THE LANCET, 1916, II., 1024

the uncertainty attaching to estimates of population, the actual deaths (in place of the death-rates) from the chief causes in the last three years are summarised in an instructive table. The most striking feature in this table is the great increase in the deaths from tuberculous phthisis and from heart disease in 1915, as compared with the year preceding the war. This abrupt rise, especially in the case of the first-named disease, may be due in part to the strain induced by war conditions and in part to the lack of new dwellings for the growing population. Balancing the gains and losses of life during 1915 in comparison with those in the previous ten years, the largest gains are found to be under the heads of pneumonia, whooping-cough, nervous disease, and diarrhoea. The losses are greatest under the heads of cancer, heart disease, and old age.

*Infantile mortality.*—Inasmuch as the mortality in the first year after birth is based, not on the numbers estimated to be living at that age, but on the number of infants born alive during the year, it is obviously unaffected by uncertainties as to population. It is also independent of the birth-rate. In the year under notice infant mortality in Manchester was at the rate of 129 per 1000 births, as compared with 112 in London, 117 in the 96 great towns, and 110 in England and Wales.<sup>3</sup> Infant mortality in the first three months of life was lower than in any previous years. It was also low in the second three months, but in the last half of the first year it was comparatively high. Compared with the preceding three years, we learn that during the first three months after birth proportionally fewer deaths occurred in 1915 from convulsions, premature birth, atrophy, and suffocation—i.e., from that class of disease which it is our main object to prevent. In the second three months the relation is less favourable. During the last half of the first year of life there were in 1915 relatively fewer deaths from whooping-cough, tuberculosis, and convulsions, but relatively more from measles, diphtheria, lung disease, and violence, the excess under lung disease being probably determined by measles prevalence.

#### *Administrative Control of Pulmonary Tuberculosis.*

Towards the close of last century a national movement was initiated for the suppression of tuberculosis. In a recent classical work<sup>4</sup> entitled "A Campaign against Consumption," by the late Dr. Arthur Ransome, then professor of public health in the Victoria University, the history of that movement was traced to its local origin half a century ago. The author asserts that the honour of being the first authority to suggest and eventually to adopt measures for the suppression of this scourge may fairly be claimed by Manchester. Dr. Ransome's own entrance into the campaign dates back to the year 1860, and to the establishment in Manchester and Salford of a weekly return of common diseases, prominent among which was phthisis. There is good reason to believe that these returns, voluntarily contributed by about 30 medical residents for more than 12 consecutive years, were not merely the forerunners but powerful incentives to the more complete notification returns which are now everywhere required under statute law. In 1884 a large area of old and dilapidated dwellings in Ancoats was officially condemned as unfit for human habitation. This area was supposed to afford shelter for 5600 persons of the poorest class, who on a five years average were succumbing to phthisis at the rate of 5·3 per 1000 living. The buildings on this area, and other insanitary areas in the older parts of the city have recently been demolished by the municipality, and better house accommodation has been provided for the displaced occupants.

*Notification of tuberculous phthisis.*—Dr. Niven will be recognised by his medical colleagues generally as one of the earliest among advocates of the compulsory notification of phthisis, as well as of its preventive treatment, as a matter of State policy. He is to be congratulated on the large measure of success he has achieved in Manchester in dealing with the administrative difficulties of the crusade—difficulties which were at one time regarded as insurmountable by many of his contemporaries. Systematic notification of phthisis is still on its trial in Manchester, London, and some other towns, and as local experience accumulates the results should materially influence administrative action.

<sup>3</sup> See table on p. 41 of Registrar-General's return for the fourth quarter of 1915.

<sup>4</sup> Published in 1915 by the Cambridge University Press. Pp. 263. Price 10s. 6d.

In the present report there appears a standard table showing the number of primary notifications during the year. This table is identical in form with that contained in Dr. Hamer's London report; and we may presume that the respective health officers will avail themselves of this and similar methods for the comparison of future results. The usual table showing the facts and rates of notification in the several districts has been prepared for 1915, but is not inserted in this report. The notification-rate exceeds the death-rate in various degrees. The case of Withington is especially notable. In this residential district the deaths steadily outnumber the reported cases, pointing to a failure in the duty of notification. The earliest records available respecting the results of notification are those for 1899—since which year more than 28,000 phthisical patients have been visited by the staff. In 25,000 cases sputum has been examined, with positive results in one-third of the cases. Not fewer than 27,106 of the patients have been isolated in hospital and the houses disinfected after removal of the patients.

The loss of life from phthisis in 1915 was in excess of the average. It was 1·76 per 1000 living of both sexes at all ages, and was above the mean rate in the preceding ten years by 0·09 per 1000. It was also above the rate in the County of London by 0·16 per 1000. When the total deaths in a single year are distributed over several age-groups in both sexes, the rate of mortality for each separate group cannot usefully be compared with corresponding rates for previous years. Nevertheless the number of deaths at each age may properly be compared, and thus an approximate idea of the course of events may be presented. By this means we learn that among males the phthisis deaths were more numerous in 1915 than in any of the preceding ten years. (This statement relates exclusively to the civil population, which includes Manchester soldiers discharged on account of phthisis.) The most marked increase occurs at ages 15-19, 20-24, and 35-74, but not at ages 25-34, nor at ages under 15. Among females also there is a corresponding excess in the deaths, the increase being nearly as great as among males. The greatest increase occurs at ages 25-34. It is possible that the additional stress of work now thrown on both sexes, and the inordinate demand for workers in the prime of life may account for the great addition to the death toll. When the deaths from bronchitis are examined similarly, they present parallel rises to those from phthisis, both among males and females. Pneumonia shows no such increase; on the contrary, among males the deaths thus returned in 1915 were fewer than in any of the preceding ten years. Among females they were fewer than in any of the ten except 1906.

*Milk and tuberculosis.*—The milk-supply of Manchester is derived from about 69 farms, chiefly in the counties of Cheshire, Derbyshire, Staffordshire, and Lancashire. During the year 91 samples of milk were examined, and in a useful table the percentages are given of farmers in each county whose milk was found to cause tuberculosis. It is noteworthy that none of the farmers in Derbyshire or in Staffordshire sent tuberculous milk to the city. In Dr. Niven's report for 1913 particulars were given of the successful manner in which the work of keeping a herd of cows free from tuberculosis is being carried on. The milk produced by this herd is still supplied to the large fever hospital at Monsall and to the sanatorium at Baguley.

*Poverty in relation to phthisis.*—A most instructive table is inserted giving a classification of the cases whose family income fell short of a standard rate according to the ascertained "shortage," and showing the institutional assistance obtained for these patients. The standard was based on that given by Mr. B. Rowntree in his book on poverty. The table indicates under several headings the numbers living and the numbers dead at the end of 1915, the numbers admitted to the several hospitals, and the number receiving institutional assistance. It would appear from this table that in 1915 phthisis was more fatal to the poorer classes of cases than in previous years.

#### *Report of the Tuberculosis Officer.*

A valuable report by Dr. D. P. Sutherland is appended to that of the medical officer of health. It contains minute details of the manifold operations of his department in the course of the year. We can only briefly refer to the analysis of cases in which the results of institutional and dispensary treatment are shown. In the "residential

department" 965 cases were treated in the several institutions, of which 505 were discharged "improved," 92 "without improvement," and 76 died. At the end of the year 221 cases remained under treatment. In the dispensary department 502 cases were treated, 212 of which were discharged as improved and 99 as without improvement, whilst 11 died. At the end of the year 132 patients still remained under treatment. Dr. Sutherland concludes his report with the encouraging statement that during the year 152 insured notified cases were found to have so far recovered that no evidence of active tuberculosis could be demonstrated; these are therefore to be regarded as arrested cases. They will, however, still remain under observation, and their health and working capacity will be reported upon periodically.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Annual Report of the Local Government Board for Ireland.*

THE annual report of the Local Government Board for the year ending March 31st, 1916, is a slim pamphlet of some 60 pages instead of the portly volume to which we have been accustomed. This economy of paper and printing has been effected by the omission of the multitudinous tables and returns which used to appear as appendices to the report proper. The tables, though not published, have been prepared as usual, and are available for reference. The figures relative to poor-relief show a rising improvement. The numbers in workhouses, including sick, aged and infirm, lunatics, idiots and imbeciles, have decreased markedly, while the numbers in the extern institutions, and more especially those receiving outdoor relief, have diminished both individually and in the aggregate. In the workhouses the deaths have decreased by 581 on the number of the previous year, and the total number of deaths from tuberculosis have decreased by 167, thus keeping up the record of diminution which has existed without a break since 1912. The deaths of infants show a decrease of 272. A graceful tribute is paid in the report to the large number of medical officers who have volunteered for service with the forces of the Crown, while the difficulty of finding adequate assistance in caring and attending on the sick poor is also commented on. The notification of tuberculosis is being gradually extended, and some local bodies have passed resolutions in favour of the general introduction of the system. The report announces with regret that "notification is not infrequently delayed until a late stage in the disease," and asks that care should be taken in all cases to notify before the infection has reached an advanced stage. Unfortunately, the Local Government Board ignores that under the conditions prescribed by the Board itself for the notification of tuberculosis it is only rarely that it is legal to notify the disease in the early stages. A medical man notifying the disease except under the prescribed conditions would leave himself open to an action for damages. In speaking of its care of the Belgian refugees thanks are given to the medical men and the hospitals of Dublin for the free advice and treatment rendered during the year.

### *Doctors of Military Age in Ireland.*

The legal adviser of the Irish Local Government Board, Dr. Vanston, K.C., has given his opinion that the Board had an absolute discretion, under Section 8 of the Act, 14 and 15 Vict., cap. 68, to refuse their approval, as they thought proper, for any reason, or without giving any reason, to the appointment of a medical officer of a dispensary district made pursuant to statute by a board of guardians. Further, Dr. Vanston states that the Letterkenny board of guardians have no power to remove Dr. Walker from the office of temporary medical officer by passing the resolution of Sept. 8th, 1916, which was *ultra vires* and of no legal effect. In the face of these facts, communicated by the Local Government Board, the Letterkenny board of guardians, by a motion passed by a majority at their last weekly meeting, have decided to instruct their solicitor to take the necessary proceedings to compel the Local Government Board to sanction Dr. J. P. McGinley's appointment.<sup>1</sup>

### *Infectious Diseases in Ireland.*

The following table in regard to infectious diseases in Ireland appeared in one of the Belfast papers of Dec. 28th, 1916. These are notifications:—

Week ending—	Dublin.					Belfast.					
	Scarlet fever.	Diphtheria	Enteric fever.	Bryspela	Total notifications.	Week ending—	Scarlet fever.	Diphtheria	Enteric fever.	Bryspela	Total notifications.
Nov. 18th ...	8	3	8	1	25	Nov. 18th ...	22	4	9	7	43
Nov. 25th ...	5	1	6	3	24	Nov. 25th ...	10	5	6	4	25
Dec. 2nd ...	7	3	2	0	20	Dec. 2nd ...	15	4	4	3	26
Dec. 16th ...	3	3	2	3	15	Dec. 16th ...	14	3	5	5	23
<b>Total ...</b>	<b>23</b>	<b>10</b>	<b>18</b>	<b>7</b>	<b>84</b>	<b>Total ...</b>	<b>61</b>	<b>16</b>	<b>24</b>	<b>19</b>	<b>122</b>

The disease "tuberculous phthisis" is now omitted. The anomalous figures under this heading were made the subject of comment in THE LANCET, when it was pointed out that, while only a few cases of phthisis were, as a rule, notified in Belfast, quite a number of notifications appeared in the Dublin list. The explanation, if such it can be called, is said to be the difficulty of notification in Ireland, to which allusion has been made. The disappearance of the figures from the official table does not lessen the difficulty.

Jan. 8th.

## THE SERVICES.

### ROYAL NAVAL MEDICAL SERVICE.

To be temporary Surgeons: A. Orr-Ewing and R. Cripps. Surg. J. R. Haldane is placed on the Retired List.

### ARMY MEDICAL SERVICES.

#### TERRITORIAL FORCE.

Capt. A. N. S. Carmichael, from attached to Units other than Medical Units, to be Deputy Assistant Director of Medical Services.

### ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. E. Brodrribb is restored to the establishment.

To be temporary Lieutenants-Colonels: Col. V. Matthews, late R.A.M.C. (Vols.), whilst specially employed; and H. M. Rigby (Capt. R.A.M.C., T.F.).

W. E. Home, Fleet Surgeon, R.N. (ret.), to be temporary Major.

To be temporary Honorary Majors: R. Armstrong-Jones and H. W. White.

To be temporary Captains: Temp. Lieut. F. W. H. Hutchinson, C. G. Whorlow, R. Williams and C. H. Treadgold.

To be Lieutenant: B. Mountain.

To be temporary Lieutenants: J. K. Watson, C. D. H. Corbett, A. B. Goldie, H. H. Fairfax, S. G. J. Dowling, A. C. S. Waters, H. H. White, F. C. Sprawson, F. Simpson, W. F. Gibb, C. M. Atkinson, A. G. Macdonald, A. B. McMaster, F. Challans, C. E. Tangye, P. J. O'Sullivan, P. A. Leighton, M. H. A. Wallie, R. O. Whyte, L. B. C. Trotter, I. G. Cobb, C. K. Smith, J. H. Mayston, H. Freeth, A. Leitch, J. Young, M. H. Raper, T. H. Macfie, B. A. Slocumbe, M. Henry, O. L. Williams, and H. G. Peel.

Temporary Captains relinquishing their commissions: J. Burfield, R. J. Jones, and T. F. Weakliam (on account of ill-health).

Lieutenants relinquishing their commissions: F. J. R. Forster, J. D. Shields, V. K. O'Gorman, and M. F. Hession.

#### TERRITORIAL FORCE.

Capt. B. Robertson, from a Field Ambulance, to be Captain.

Capt. H. M. Rigby, Capt. E. D. Macnamara, and Capt. A. D. Reid are seconded whilst holding temporary commissions in the R.A.M.C.

Capt. J. M. Hunt to be temporary Major.

Capt. H. G. F. Dawson to be Major.

Lieutenants to be Captains: F. F. T. Hare, S. Childe, and C. P. Sells.

Capt. (temp. Major) J. E. W. Mac Fall relinquishes his temporary rank on ceasing to command a Field Ambulance.

Capt. (temp. Major) J. Young to be temporary Lieutenant-Colonel whilst commanding Field Ambulance.

Lieut.-Col. F. J. Knowles, from Territorial Force Reserve, to be Lieutenant-Colonel, without pay or allowances.

Capt. F. B. Smith, from a Field Ambulance, to be Captain.

Captains relinquishing their commissions: E. P. Dawes, W. H. Calvert, and B. S. Wills.

#### TERRITORIAL FORCE RESERVE.

Capt. W. N. W. West-Watson, from a casualty clearing station, to be Captain.

#### SPECIAL RESERVE OF OFFICERS.

Lieut. (on probation) R. R. Scott is confirmed in his rank.

#### INDIAN MEDICAL SERVICE.

Temporary Lieutenants to be temporary Captains: Kamberanda Karap, Mandara and Jeangir Kalkhusro Nariman.

The retirement of Capt. Jogesh Chandra Dey has been confirmed by the King.

<sup>1</sup> See THE LANCET, 1916, ii., 497.

Col. W. W. Clemensha, Sanitary Commissioner with the Government of India, is at present working temporarily as health officer of Delhi, pending the arrival of a permanent incumbent.

#### DEATHS IN THE SERVICES.

Surgeon-General Sir Edmond Townsend, K.C.B., C.M.G., A.M.S., on Jan. 3rd, at his residence, Clontymon, Co. Cork, aged 71, after a long record of active service. He entered the Army in 1867 and served in the Abyssinian campaign 1867-68 (medal), in the Malay Peninsula 1875-76, where he was severely wounded (medal with clasp), and in the Zulu war, where he was present at the battle of Alundi in 1879 (mentioned in despatches). He also served in the Egyptian war of 1882, including Kassassin, Tel-el-Kebir (medal with clasp and Khedive's Star), in the Burmese Expedition 1885-86 (medal with clasp), and in the Ashanti Expedition (mentioned in despatches and star). He was with the forces in the North-Western Frontier of India campaign 1897-98. Principal Medical Officer with the Mahratta Field Force and Principal Medical Officer with the 1st Division in the Tirah Expeditionary Force (mentioned in despatches, C.B., and medal with two clasps). In the South African war of 1899-1902 he was Principal Medical Officer with the 1st Division and afterwards in the Western District (dangerously wounded, mentioned in despatches, C.M.G., Queen's medal with four clasps, and King's medal with two clasps). From 1902 till his retirement from the service in 1905 he was Principal Medical Officer at Netley

#### VITAL STATISTICS.

##### HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns 969 births and 872 deaths were registered during the week ended Saturday, Dec. 30th, 1916. The annual rate of mortality, which had increased from 13·8 to 19·6 per 1000 in the four preceding weeks, fell to 19·2 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 15·3, against 15·6 per 1000 in the large English towns. Among the several towns the death-rate during the week ranged from 9·3 in Ayr, 11·4 in Leith, and 13·7 in Clydebank, to 23·0 in Perth, 26·7 in Hamilton, and 29·9 in Dundee.

The 872 deaths from all causes were 20 fewer than the number in the previous week, and included 50 which were referred to the principal epidemic diseases, against 37 and 46 in the two preceding weeks. Of these 50 deaths, 13 resulted from infantile diarrhoeal diseases, 11 each from whooping-cough and diphtheria, 10 from measles, 3 from scarlet fever, and 1 from enteric fever. The annual death-rate from these diseases was equal to 1·1, against 0·7 per 1000 in the large English towns. The deaths from infantile diarrhoea, which had been 14, 10, and 9 in the three preceding weeks, rose to 13, of which 9 occurred in Glasgow. The deaths referred to diphtheria, which had been 6, 3, and 6 in the three preceding weeks, rose to 11, and included 4 in Glasgow and 2 each in Edinburgh and Dundee. The fatal cases of whooping-cough, which had been 3, 7, and 12 in the three preceding weeks, numbered 11, and comprised 4 in Glasgow, 3 in Edinburgh, and 2 in Leith. The deaths attributed to measles, which had been 12, 11, and 14 in the three preceding weeks, fell to 10, of which 8 occurred in Dundee. The 3 deaths from scarlet fever were slightly below the average in the earlier weeks of the quarter. The 2 fatal cases of enteric fever occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had increased from 118 to 227 in the four preceding weeks, further rose to 240 in the week under notice, and were 85 above the number registered in the corresponding week of 1915. The deaths from violence numbered 27, against 34 and 33 in the two preceding weeks.

##### HEALTH OF IRISH TOWNS.

In the registration area of Dublin 130 births and 216 deaths were registered during the week ended Saturday, Dec. 30th, 1916. The annual rate of mortality, which had increased from 17·7 to 25·6 per 1000 in the four preceding weeks, further rose to 28·4 in the week under notice, against 23·7 per 1000 in London.

The 216 deaths from all causes included 24 of infants under 1 year and 73 of persons aged 65 years and upwards. Five deaths were referred to infantile diarrhoea, 4 to measles, 2 to whooping-cough, and 1 to scarlet fever. The causes of 19 deaths were uncertified, and those of 9 others were the subject of coroners' inquests, while 79, or 37 per cent., of the total deaths occurred in public institutions.

During the same period 133 births and 159 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 21·3 per 1000, and included 14 of infants under 1 year and 52 of persons aged 65 years and upwards. Two deaths were referred to infantile diarrhoea and 1 each to measles and diphtheria. The causes of 5 deaths were uncertified, 8 inquests were held, and 38 of the total deaths occurred in public institutions.

**RUSSIAN MEDICAL SCHOLARSHIPS.**—The director of the Higher Institute of Medicine for Women at Petrograd has received an anonymous gift of £20,000 for the foundation of scholarships in the name of Count Vorontzoff, who died last year.

**CENTENARIANS.**—Mrs. Elizabeth Symons, of Church Town, Crowan, died recently, aged 102 years and 10 months. She is stated to have been the oldest person in Cornwall.—Mr. Samuel Stidwill, of 6, Union-street, Stonehouse, Plymouth, died on Dec. 26th, 1916, aged 102 years.—Mrs. Harriet Godland died recently at an almshouse in Ilton, Dorset, in her 104th year.—Mrs. Mary M'Quade, Omeath, S. Louth, died on Jan. 4th at the remarkable age of 110 years. She spoke English and Irish fluently, and is said to have been the oldest woman in Ireland. She resided all her life at Omeath, and her age has—it is stated in the papers—been verified by church records.

#### Correspondence.

"Audi alteram partem."

#### THE LIQUOR TRAFFIC AND THE FOOD QUESTION.

To the Editor of THE LANCET.

SIR,—In your leading article under this title you comment on the effect of the regulations of the Liquor Control Board in decreasing drunkenness and alcoholic disease as measured by the most characteristic manifestation of alcoholism, delirium tremens. In the report of the Liquor Control Board, issued a few days ago, statistics are given which show a reduction in the number of female convictions for drunkenness of 43·8 per cent. in England and 37·7 per cent. in Scotland, and the Board regards these figures as effectively disproving the common assertion that, while drunkenness among men may have diminished, it has increased among women. My experience as physician-in-charge of the alcoholic wards in the Royal Infirmary, Edinburgh, leads me to believe that there is an important fallacy in the data founded on; and it is in the public interest at the present time that attention should be drawn to it.

During the past year there has been a very unusual strain on the wards in question, and more especially for female patients. The number of patients suffering from acute alcoholism—nearly all brought in by the police—who were sufficiently ill to necessitate their being treated as in-patients was double the average of previous years. The accompanying table shows the record for admission of men and women, and also the number of women arrested for drunkenness during the same period:

	Admissions to wards.		Arrests for drunkenness. Females.
	Males.	Females.	
1913	198	52	1719
1914	185	51	1961
1915	169	53	1721
1916	151	108	1222

This increase in alcoholic cases is confirmed in the experience of the out-patient department of the hospital, where less serious cases are treated for injuries received under the influence of liquor; statistics on this point are not, however, available, as the patients are classified according to the surgical conditions.

We have, therefore, an anomalous position, the experience of the hospital pointing conclusively to a marked increase of alcoholism among women; the statistics of the police under the headings of "Convictions for Drunkenness" and "Arrest for Drunkenness" pointing in the opposite direction.

If the experience in Edinburgh can be taken as an index of conditions obtaining elsewhere, it seems clear that the Liquor Control Board is hardly justified in the conclusion it has drawn from the data supplied by the police reports. I am aware that in former reports the Liquor Control Board has given statistics in regard to admissions for delirium tremens, mostly, I think, in English hospitals. In this connexion it is important to keep in mind that, in Scotland at any rate, only a proportion, and a small one, of cases of acute alcoholism come into the category of delirium tremens.

I am, Sir, yours faithfully,

Edinburgh, Jan. 8th, 1917. CHALMERS WATSON, M.D. Edin.

\* \* The curious discrepancy to which Dr. Chalmers Watson calls attention is explained by the Prison Commissioners, to whose report we allude in another column. Fewer women have been convicted of drunkenness, but the average number of convictions per individual has risen to such an extent as actually to increase the total number of convictions.—ED. L.

To the Editor of THE LANCET.

SIR,—I have read the leading article on the liquor traffic and the food question, in which you comment adversely on total prohibition. In the first place you say its enforcement would not be easy. Why not? If the conscription of our

sons has been attained, why not the conscription of our luxuries? It is the easiest and only way of solving the liquor question; all else is mere tinkering with the evil. Secondly, you put up a problematical case of evil resulting from the sudden cessation of alcohol, especially in elderly men who have been accustomed to it, and dwell on the possibility of restricted output on this account. This theoretical diminution, which I dispute, would be a mere drop in the bucket compared to the actual diminution which is at present going on in munition works from over-indulgence in alcohol by workers who carry it in, and find opportunities to consume it at their work. Prohibition would undoubtedly vastly increase the output of war munitions, at least, in Glasgow and Clyde district. Your third argument against prohibition is the use of other substances—methylated spirit, varnish, lacquer, and the poisonous effects on those who drink them. Why should we distress ourselves about these degenerates who will not deny their appetites? Is it for the protection and preservation of this portion of our race that we are sending our sons into battle?

Your alternative to prohibition of imposing restrictions in the hours of sale and quality of liquor as advocated by the Liquor Control Board has been a complete failure in Scotland. In to-day's *Glasgow Herald* an Edinburgh doctor gives statistics showing that in the Royal Infirmary there the number of acute alcoholic cases admitted to the female ward was twice as great as in 1913-14, although the convictions for drunkenness in the police courts had fallen by 500. A publican patient of mine tells me that he is quite satisfied with the restricted hours of sale as he is selling a half more liquor than before it with less labour and expense. The long queues of women seen in Glasgow lately waiting to get bottles filled before the New Year closing days show the utter futility of these restrictions, and the after-results are seen in our own Royal Infirmary, where probably one-half of the surgical cases are the direct result of alcoholic indulgence. When you know of women admitted there this week with their faces trampled on by drunken husbands and another jumping out a second-storey window to escape from the violence of a drunken madman you can only conclude that the total prohibition of alcohol is the only efficient way.

If a new disease were to make its appearance in the land bringing in its train one tithe of the wastage and suffering to innocent people that alcohol does it would not be tolerated for a moment. State ownership would not cure the drinking habits of Scotland—they don't care who owns the public-house, their object is to get enough to make them feel the effects of the alcohol. Till we as a nation get a Government that will help us to purge ourselves from our national sins we cannot hope, nor do we deserve, to win the war.

I am, Sir, yours faithfully,  
JAMES DUNLOP, M.B., C.M. Glasg.

Glasgow, Jan. 6th, 1917.

\*\* No one contradicts much of what Dr. Dunlop says. It is common knowledge. The enforcement of prohibition, on which we did not comment adversely, is difficult, because a vested interest, subject to good conduct, has been recently conferred upon owners of licensed properties. The actual circumstances have to be looked at, lest in the search for what may later be the best we lose the present good.—ED. L.

## AGGLUTINATION REACTIONS IN TYPHOID AND PARATYPHOID FEVERS.

To the Editor of THE LANCET.

SIR,—It would appear from recent publications that Dreyer, Ainley Walker, and Gibson are of opinion that they were the first to realise the fact that repeated agglutination tests are necessary before arriving at a definite diagnosis in cases of the enteric group in inoculated men.

In a paper published by them in THE LANCET, 1915, i., 324, they made the following statement when dealing with this subject:—

It is probable that the absence of accurate diagnosis in the past explains the fact that statistical results arrived at in our Army have not always been so convincing as would otherwise have been the case.

The above remark is quite untrue of later years and an injustice to officers of the Royal Army Medical Corps.

I feel that it is only right to point out that repeated observations by the macroscopic method of the serum agglutinin content in cases of suspected typhoid and paratyphoid fevers have been taught at the Royal Army Medical College, and carried out by Army bacteriologists since the re-introduction of typhoid inoculation in the Army in 1905.

The necessity for using Dreyer's technique to arrive at reliable results, as suggested in a paper by Ainley Walker in THE LANCET of Nov. 25th, 1916, is not apparent, and equally reliable results can be and have been obtained when using a living suspension of bacilli, provided the suspension is standardised.

The following extracts will show that repeated observations were found to be necessary in past years, and it will be noted that these extracts are from reports and papers published some time before the appearance of papers by Dreyer, Ainley Walker, and Gibson; in fact, before they had probably had very many opportunities of noting the serum reactions in inoculated individuals suffering from fevers of the enteric group, especially in the case of paratyphoid A fever, which rarely found its way west of Suez before this war.

The first is from an abstract of report on the enteric fever dépôt at Naini Tal, taken from the annual reports of divisional sanitary officers in India for 1908, published in 1909.

Some of these errors in diagnosis are due to the fact that the men had been inoculated, and therefore their blood gave a positive Widal reaction, and they were diagnosed enteric fever on the strength of this alone. In all cases of fever in inoculated men the blood should be taken near the beginning and towards the end of the fever. If the two results are the same the case is probably not enteric. If there is a marked rise in the agglutination titre the case is certainly one of enteric fever. Every case of true enteric fever should give a complete reaction in a dilution of 1/100 at some period of the disease. In the case-sheets of many of the men sent here it is noted "Widal reaction 1/40." Now nearly all inoculated men will give a positive reaction in this dilution for months and in some cases for years after inoculation.

Again, in the 1910 report from the same dépôt we find the following:—

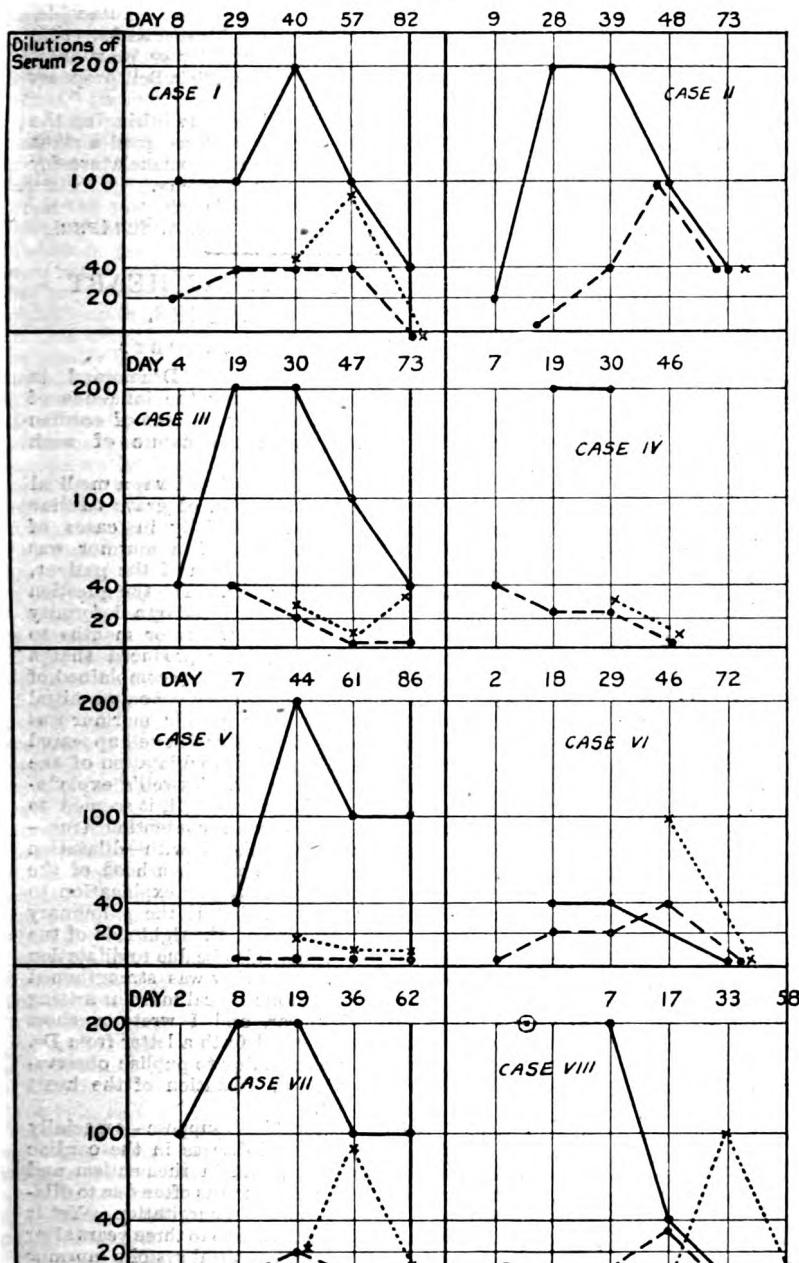

In paratyphoid fever the Widal reaction is invariably raised for the *B. typhosus*, especially during the first week of fever, and may be just as high for this bacillus as that shown during an attack of ordinary enteric fever. The reaction for para. A is as a rule lower and may only be present in such dilutions as 1/20 and 1/40 and possibly only a trace in the latter; it is also as a rule transient and may only be found for a few days in the later stages of the disease or early days of convalescence, and as a rule disappears in a few weeks, although in some cases we have found it a year after the fever. The group agglutinins for typhoid also disappear rapidly in contrast to the specific agglutinins after an attack of true typhoid fever, which remain raised for months and years in some cases. Thus we have the apparent anomaly of a man passing through a fairly severe attack of enteric fever (clinically) and giving a few weeks later an entirely negative reaction. This has happened here in several cases from whose blood the *B. para. A* had been isolated and whose agglutination titre had (during the fever) been high for both typhoid and para. A. In some cases, also, the paratyphoid reaction may entirely disappear, leaving a raised titre for *B. typhosus*, and again very rarely the titre for paratyphoid may remain raised without any agglutinins for *B. typhosus*.

An article published in the *Journal of the Royal Army Medical Corps* also points to the fact that army bacteriologists were quite alive to the importance of repeated Widal estimations in 1910. The paper referred to is "An Inquiry into a Small Epidemic of Paratyphoid Fever in a Camp in India," by Major H. W. Grattan, R.A.M.C., and Major D. Harvey, R.A.M.C.<sup>1</sup>. In this epidemic all the men who contracted the fever were inoculated against *B. typhosus*, and it is interesting to note that the bacillus was recovered from the blood in every case but one. The charts of the agglutination curves were published and are here reproduced. (See Chart I.)

To take another example. Chart II. is from a paper published in the *Journal of the Royal Army Medical Corps*, 1911, xvii., showing agglutination curves in a case of

<sup>1</sup> Journal of the Royal Army Medical Corps, 1911, xvi., 9.

CHART I.

paratyphoid A fever occurring in a man inoculated against *B. typhosus*.

This paper by Major H. W. Grattan, R.A.M.C., and Captain J. L. Wood, R.A.M.C., gives an excellent account of the serum reactions of cases of paratyphoid A fever in inoculated men, and also mentions the frequency of the low titre of the serum for para. A. This point Professor Dreyer laid stress on at a meeting of the Royal Society of Medicine on Nov. 9th, 1915. His words at the meeting were :—

..... In every case bacteriologically proved to be a typhoid or paratyphoid B infection, the agglutination method gave a positive diagnosis (i.e., 100 per cent. of the cases), while in the case of paratyphoid A infection the agglutination test failed in only about 7 per cent. of the cases. Why are the

results with paratyphoid A relatively so poor? The reason is that for a considerable time I did not know how low is the agglutination given by paratyphoid A in certain cases.

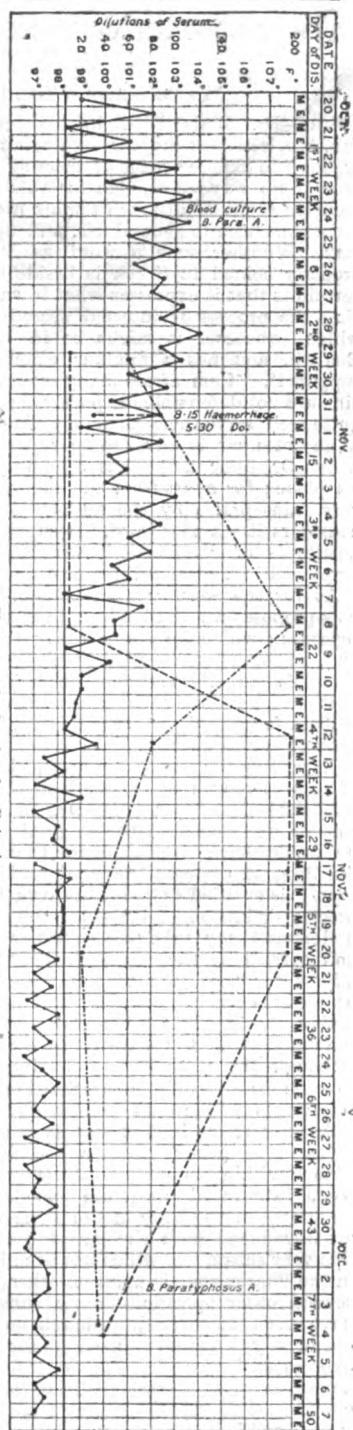

This in the year 1915, and after he had been working with the two officers mentioned above, while all of the papers referred to in this communication were published before the end of 1911. The evidence brought forward will, I think, establish the fact that bacteriologists in the service were not quite so behindhand in the bacteriology of the enteric group of fevers as Drs. Dreyer, Ainley Walker, and Gibson would lead us to believe.

I am, Sir, yours faithfully,

H. GRAEME GIBSON,  
Captain, R.A.M.C.

Royal Army Medical College, Dec. 30th, 1916.

CHART II.

## THE NOMENCLATURE OF "INTERNAL SECRETION."

*To the Editor of THE LANCET.*

SIR.—Dr. Blair Bell, in his letter in your issue of Jan. 6th, censures me for employing the term "endocrine organs" to denote organs of internal secretion. I am, however, in no way responsible for this term, as Dr. Blair Bell seems to suppose, although I think it convenient. It has for some time been in general use, and appears to have come to stay. Whether such a word as "endocrine" could be properly coined in Greek is beside the question. What is certain is that it expresses what is wanted to be expressed—viz., the process of internal secretion, by a simple word, which, whatever it might be in Greek, is good enough English, and has a familiar example in "endogen" to support it. I am afraid many scientific terms used in medicine are not defensible on purely etymological grounds, yet quite well serve their purpose. The term "endocrine" is at any rate hardly likely to be superseded by "endocrinio," which Dr. Blair Bell "has been in the habit of using" in its place; for apart from the fact that it is damned with very faint praise by the author of its being, who himself considers it "a poor word," it suggests to a physiologist the antithesis of "epicritic," which Head and Rivers have employed in a totally different connexion.

As for the word "hormopoietic," which Dr. Blair Bell now proposes we shall adopt in place of "endocrinio," and regarding which he states that "the derivation is obvious and, he thinks, unassailable," a glance at a lexicon shows that this can only be derived from *ὅρμος*, a chain or cord, so that the internally secreting organs thus become either "chain-factories" or "rope-walks," which, as old Euclid used to say, is absurd!

Regarding the term "hormone," I have given the history of this at length in my book on the "Endocrine Organs," published last year. If Dr. Blair Bell had looked at this or had consulted the original papers referred to in it he would have avoided more than one error. Professor Starling, who coined the word, and who, as Dr. Blair Bell says, "is entitled to define his own term," has given a very precise definition of it<sup>1</sup>—viz: "By the term 'hormone' I understand *any substance* normally produced by the body and carried by the blood stream to distant parts which it affects for the good of the organism as a whole." He proceeds to give as examples of hormones, secretin, adrenalin, and carbonic acid.<sup>2</sup> I myself propose to use the word "hormone" in the wide sense employed by its inventor, although Dr. Blair Bell, following most authors, appears to wish to limit Professor Starling's definition to certain substances produced in definite organs.

As long ago as 1894 it was shown by the late Dr. George Oliver and myself that a specific organic substance is formed within the medulla of the suprarenal capsules which, when introduced into the blood, operates upon certain structures in the body in the same manner as drugs which are introduced from the outside; and, as a matter of fact, this very substance, which has been isolated, is now included in the Pharmacopoeia amongst other drugs. Since that time several other specific organic substances of like nature have been discovered, although no other has as yet been chemically isolated. Seeking for a convenient term to express such specific organic substances, whatever their action might be, and realising my own classical shortcomings, I consulted with my friend and colleague, the late Professor W. R. Hardie, than whom, I suppose, our generation has seen no more accomplished classical scholar. It was he who suggested the term "autacoid" (not autocoid, as Dr. Blair Bell is made to put it, owing, I trust, to a printer's error), derived from *άὐτος*, a remedy (whence also the term *panacea*, a universal remedy); and since this exactly expresses what is required—viz., a drug-like substance formed by the body itself—I adopted the term, defining an autacoid as a "specific organic substance formed by the cells of one organ and passed from them into the circulating fluid to produce effects upon other organs similar to those produced by drugs." But, like other drugs, autacoids either excite action or prevent action, and for clarity's sake it is not only convenient but necessary to have two words

expressive of these opposite effects. To express excitation I adopted Professor Starling's term "hormone," which was already in general use; to express prevention the term "chalone," from *χαλώω*, to make slack. Thus the autacoids, as well as other drugs, could be classed either as *hormonic* or *chaloneic* according as they excite activity or prevent it. To talk of provoking prevention, as Dr. Blair Bell proposes to do, is a contradiction in terms.

I may, I hope, be permitted to add without infringing the bounds set by modesty, that I have at least as good a right as Dr. Blair Bell to suggest an appropriate nomenclature for what is after all to some extent my own progeny.

I am, Sir, yours faithfully,  
University of Edinburgh, Jan. 9th, 1917. E. A. SCHÄFER.

## THE DIFFERENTIATION OF HEART MURMURS IN SOLDIERS.

*To the Editor of THE LANCET.*

SIR.—The remarks of Professor David Drummond in THE LANCET of Nov. 4th last regarding the influence of pressure upon the chest wall in altering the tone of cardiac murmurs suggest a comment upon the nature of such murmurs.

A systolic apical murmur in the days when I was a medical student was looked upon as an indication of grave cardiac trouble. We examined the heart carefully in cases of rheumatic fever, and the appearance of a murmur was virtually considered to justify condemnation of the patient, so far as health was concerned, for life. Yet the question arose how, if mitral regurgitation is occasioned by a deformity of the mitral valve which must take weeks or months to develop, can regurgitation be so quickly produced that a murmur may appear almost as soon as pain is complained of in the joints? Again, it was soon noticed that not only a mitral systolic murmur but also a pulmonary systolic murmur was often present. Then a paper by Dr. Arthur Foxwell appeared attributing a pulmonary systolic murmur to dilatation of the right side of the heart. Although Dr. Foxwell's explanation may not have been correct in every detail, it seemed to be reasonable, and probably his main contention true—namely, that the murmur is associated with dilatation of the right ventricle, chiefly in the neighbourhood of the conus arteriosus. Accepting Dr. Foxwell's explanation to be true, it was natural to conclude that if the pulmonary systolic murmur be due to dilatation of the right side of the heart, a mitral systolic murmur may also be due to dilatation of the left side of the heart. This view was strengthened by noticing how frequently a systolic apical murmur arising during rheumatism may disappear, and I wrote a short article in THE LANCET<sup>1</sup> which called forth a letter from Dr. D. B. Lees, saying that he was intending to publish observations which supported the view of dilatation of the heart occurring in acute rheumatism.

At that time it seemed reasonable to suppose—especially after meeting with definite cases of disease in the cardiac muscle in the post-mortem room, both in rheumatism and chorea—that the mitral systolic murmur was often due to dilatation of the heart allowing of mitral regurgitation. Yet it became evident, when looking up cases two to three years after a murmur had first been noted, that a mitral systolic murmur which had developed a harsh character before the patient first passed from under observation generally persisted, whereas a murmur described as lower-pitched more often than not disappeared. This gives rise to the question, What is the difference in causation of a low-pitched and of a high-pitched murmur? Can a systolic apical murmur be produced without the presence of regurgitation through the mitral orifice? Is it possible that the murmur may arise in the cardiac wall?

Professor David Drummond has recently commented upon the effect of pressure on the chest-wall upon cardiac murmurs, laying stress on the fact that many murmurs can be abolished by pressure. In my experience it is the low-pitched murmurs which are very materially affected, but I do not think are often completely abolished, by pressure. The lower tones disappear, but a residuum of higher tones of more blowing character may remain. We may assume that the higher-pitched tones possibly indicate some temporary leakage through the mitral valve. But how are the lower

<sup>1</sup> Proc. Roy. Soc. Med., 1914.

<sup>2</sup> The italics are mine.

<sup>1</sup> THE LANCET, 1896, II, 170.

tones which disappear produced? In one detail I misread the letter of Professor Drummond when I recently ventured to add a note on my experience regarding the effect of pressure upon the chest-wall on murmurs. Professor Drummond appears to consider that the murmurs which disappear are due to vibrations of the chest-wall. It is difficult quite to gather his meaning. The chest-wall being the medium which, through the stethoscope, conveys murmurs to our ears must vibrate in all cases, but neither with functional nor organic disease can murmurs, it seems to me, originate in the chest-wall. If we abolish a murmur by pressure upon the chest-wall we presumably arrest the onward progress of those vibrations which compose the murmur. In those murmurs which we do not abolish the vibrations are of a different nature, probably smaller and more rapid, and pressure fails materially to influence them. Earlier I have suggested whether it may be possible that a systolic murmur may arise in movements of the heart-wall. In this connexion it may be interesting to remark that so frequently are slight functional murmurs audible both over the pulmonary and mitral areas in very young children that it seems to me they may be regarded as physiological. In other words, cardiac action alters to some extent as age advances and some time may elapse before the cardiac sounds we are familiar with in adults become the fixed sounds of the heart. If we allow the view that some low-toned functional murmurs are produced by vibrations arising in unusual behaviour of the cardiac systole then perhaps we may consider some cases in which functional murmurs are heard to be a return to the comparatively unstable condition of early childhood.

Whatever view may be held with regard to the possibility of functional apical systolic murmurs arising in the wall of the heart, in cases where a diastolic sound is audible between the first and second sound we have definite evidence of some abnormal cardiac action. An additional shock to that of the impulse can often be felt by the hand, and when the heart is diseased and much hypertrophied the abnormal impulse may, in rare instances, give a tracing in which the wave it indicates, though more transitory, may equal the wave of the systole in height. We are, however, speaking more particularly of hearts in which there is no disease. In them, although it is not so easy to obtain a graphic record of abnormal cardiac action, the same action is very commonly present. It may persist for days or weeks or be present at one moment and absent at another. The point, however, on which I wish to lay stress is that a diastolic sound occurring between the first and second sounds is associated with some abnormal cardiac action. This action may be an exaggeration of a physiological action. The frequency of its presence in children supports such a view. But the action, when present in a marked degree, is abnormal as far as the adult is concerned. The sound which appears in association with the abnormal action must also be regarded an abnormal, but as a rule is of no serious import. Yet I have known it frequently to be mistaken by well-qualified men for a pre-systolic murmur, and the subject of it to be diagnosed as a sufferer from mitral stenosis. The sound itself, however, need in no way be connected with valvular disease, and in most instances is merely an indication of some passing phase of cardiac action.

To sum up the foregoing remarks, it may be said that so-called functional murmurs are, as a rule, lower in tone than those having an organic origin. They are more materially affected by pressure. Although in the case of apical murmurs some temporary leakage of the mitral valve may be present, the question arises whether that portion of the murmur which can be readily abolished by pressure may not be due to vibrations associated with an abnormal cardiac systole. In favour of this view is the fact that in association with a dia-tolic sound, occurring between the first and second sounds, there is obviously an unusual action of the heart, which in most instances, being transitory, must be described as functional.

Since writing the above an observation, I believe of Sir Wm. Broadbent, has occurred to me, which may be worthy of note at the present time when so many soldiers who have undergone severe physical exertion are under medical supervision. Sir Wm. Broadbent, so far as I remember (I quote from memory), without referring to the theory of Dr. Foxwell concerning the method of production of the pulmonary systolic murmur, stated that he had met

with cases in which healthy young men manifested pulmonary systolic murmur after prolonged physical exertion, such as mountain climbing. It would be interesting if this observation should be confirmed. It may be added also in connexion with the effect of pressure upon cardiac murmurs that I believe my attention was first drawn to the fact by a paper published by Dr. Sydney Ringer and Dr. A. G. Phear many years ago. Dr. Moxon once said that the "art of originality is the art of forgetting." There may occasionally be experiences with which one becomes so familiar that one forgets whether they first impressed themselves upon one's mind in virtue of their own force or whether some other observer has drawn one's attention to them.

I am, Sir, yours faithfully,

THEODORE FISHER, M.D. Lond.

### STAPHYLOCOCCUS MENINGITIS.

*To the Editor of THE LANCET.*

SIR.—The diagnosis of the case described as staphylococcus meningitis by Dr. H. Bourges in your issue of Jan. 6th (p. 28) would appear likely to be at least doubtful. Contamination by *Staphylococcus albus* in my experience in lumbar puncture, however carefully the skin is prepared is fairly frequent, both in cases where the meningococcus is found and where it is not found. Gram-positive cocci in any turpentine abscess of some duration would not be uncommon. Authorities agree that many cases of cerebro-spinal fever occur where the causative organism which is very elusive is not found. The description of the case and the fact that the patient recovered makes it likely to be one of cerebro-spinal fever rather than one of staphylococcus meningitis.

In reference to this contamination you published a few issues back the description of a puncture needle specially designed to obviate its contamination by the operator's fingers. I find a simpler method is to flame the head of the needle after puncture and before withdrawing the stilette to collect the fluid.—I am, Sir, yours faithfully,

SHEFFIELD NEAVE,  
Temporary Captain, R.A.M.C.  
Military Laboratory for Cerebro-spinal Fever, Ipswich,  
Jan. 7th, 1917.

### A NEW CULTURE MEDIUM FOR THE MENINGOCOCCUS.

*To the Editor of THE LANCET.*

SIR.—In a recent investigation into the anti-coagulating action of acid aniline dyes on proteins, Holland<sup>1</sup> found that blood serum could be heated to high temperatures with these dyes without undergoing coagulation. He stated that blood serum, to which was added half its volume of a 2 per cent. solution of Congo red, set to a clear jelly after sterilisation at 120° C., and could be used as a culture medium for bacteria. This fact appeared to the writer, who had been doing much culture work with the meningococcus, to offer an easily prepared medium upon which that organism could be grown readily, and which could be used for plate cultures. Accordingly, sloped tubes of the Congo red serum were prepared in the inspissator, and it was found that the medium was transparent, at any rate, in the upper portion of the slope, although in the lower portion the colour was somewhat too dense to be accurately described as absolutely transparent. The top thin part of the slope was inclined to become hard. Stroke cultures of meningococcus on the new medium grew well, and discrete red colonies were plainly visible in the upper part of the stroke when examined with a lens through the medium. The viability of the organism in these cultures was quite good, subcultures being obtained after two to three weeks. The cultures also yielded the characteristic sugar reactions of the organism.

Plates of the new medium were prepared by pouring the liquid mixture into the plate and sterilising at 120° C. for 20 minutes. There being a considerable amount of expressed water, it was found inadvisable to use the inverted position for drying off the plates. The surface of the medium was somewhat soft, but it was quite transparent, and colonies could readily be examined under the microscope. An opportunity has not yet arisen for using these plates for obtaining

<sup>1</sup> Comptes Rendus, vol. cixii., p. 959.

cultures from throat swabs, but it is possible that plates of this medium might form a useful separation method for direct cultures from the throats of meningococcal contacts. In passing, it may be mentioned that the *B. diphtheriae* grows well on the new medium.

In connexion with the keeping of laboratory cultures of the meningococcus on serum agar and ascitic fluid media, the necessity for frequent subcultivation is well known. The claims of ordinary blood serum for this purpose would appear to have been somewhat overlooked. It has been found that Loeffler's serum forms a medium on which the meningococcus is long-lived. On more than one occasion the coccus has been found to be alive in cultures one month old. Either the new Congo red serum or Loeffler's serum is recommended for laboratory cultures of meningococcus, the tubes being kept in the incubator and subcultures made every fortnight.—I am, Sir, yours faithfully,

J. H. JOHNSTON, M.Sc.

Arundel-street, Strand, W.C., Jan. 6th, 1917.

### THE HOT-AIR OVEN AS AN INSPISSATOR.

To the Editor of THE LANCET.

SIR,—In the absence of an inspissator in the bacteriological laboratory I have found that the hot-air oven can be utilised as such to far greater advantage than with the water-bath, the inspissator's usual substitute. Two pieces of glass rod calculated to give the required slope to the serum in the test-tubes are fixed by means of plasticine to a sheet of asbestos, the tubes of serum laid across each rod, and the whole placed in the oven. The purpose of the asbestos is to prevent any charring which might occur if the tubes were placed on the floor of the oven without any protection owing to the proximity of the Bunsen heater. I have found inspissation for 30 minutes at 80° C. ample in the majority of cases by the above method.

The great advantages of this technique are that it is a great deal quicker than with the water-bath, and the dimensions of the hot-air oven being generally in excess of those of the former a greater number of tubes can be inspissated at one time.

I am, Sir, yours faithfully,

E. L. COOPER,

Jan. 1st, 1917. Bacteriologist, No. 14 Mobile Field Laboratory.

UNIVERSITY OF EDINBURGH.—We have received from the secretary of the Senate the annual report for 1916, containing the following items of medical interest. The total number of matriculated students during the year was 1741, of whom 1060 were men and 681 were women. Of these, 941 (including 238 women) were enrolled in the Faculty of Medicine. Of the students of medicine, 446 belonged to Scotland, 143 were from England and Wales, 34 from Ireland, 79 from India, 216 from British colonies and dependencies, and 23 from foreign countries. The number of medical students from the colonies and dependencies was 23 in excess of the number for 1915, South Africa accounting fully for the increase. The following medical degrees were conferred during 1916: Bachelor of Medicine and Master in Surgery (M.B., C.M.), 1; Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), 128; Doctor of Medicine (M.D.), 18. The total annual value of the University fellowships, scholarships, bursaries, and prizes in the Faculty of Medicine now amounts to £5565. Women students of medicine, who formerly received their education in extra-mural classes, have been admitted to University courses in all the subjects of the medical curriculum. An Ordinance is being promoted for the foundation of a chair in tuberculosis, funds amounting to £18,000 having been transferred for this purpose to the University Court by the Royal Victoria Hospital Tuberculosis Trust. Additional lecturers have been appointed in the Faculty of Medicine as follows: in pathology, Dr. James Miller; in materia medica, Dr. John Orr; in midwifery, Dr. J. W. Ballantyne. Mr. J. W. Dowden has succeeded Mr. C. W. Cathcart as one of the senior lecturers in clinical surgery. On Feb. 15th the death occurred of the venerable Principal, Sir William Turner, at the age of 84. His active association with the University—as demonstrator in anatomy, as professor of anatomy, and as Principal—extended over 62 years. The vacancy in the Principalsip was filled up by the appointment, in May, of Sir J. Alfred Ewing, Director of Naval Education at the Admiralty.

### The War.

#### THE CASUALTY LIST.

The following names of medical officers appear among the casualties announced since our last issue:—

##### Died.

Lieut.-Col. R. C. McLeod, Canadian Army Medical Corps, was a student at New York University Medical College, and was licensed in 1891. Before joining the Canadian Contingent he was in practice at North Sydney, Nova Scotia.

##### Wounded.

Capt. C. E. Whitehead, R.A.M.C.

Capt. J. H. Askins, R.A.M.C.

Capt. T. P. Cole, R.A.M.C., attached Royal Field Artillery.

Lieut. D. Campbell, R.A.M.C.

#### DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Capt. and Flight-Commander J. W. W. Nason, Royal Sussex Regiment, and Royal Flying Corps, younger son of the late Dr. C. St. S. R. Nason, of Corse Grange, Gloucester. Second Lieut. R. N. Heathcote, East Yorkshire Regiment, only surviving son of Dr. R. Heathcote, West Didsbury, Manchester.

Second Lieut. W. D. Semple, King's Royal Rifle Corps, eldest son of Col. Sir D. Semple, Director-General, Public Health Department, Egypt.

#### MENTIONED IN DESPATCHES.

The names of the following officers of the medical services, whose "distinguished and gallant services and devotion to duty" he considers are deserving of special mention, are included in the recent despatch from Field Marshal Sir Douglas Haig, G.C.B., Commander-in-Chief of the British Armies in France:—

##### STAFF.

Black, Maj. R. B., R.A.M.C., Res. of Off.

Burtschell, Col. C. H., C.M.G.

Macpherson, Surg.-Gen. W. G., C.B., C.M.G., Hon. Phys. to the King.

Sloggett, Lt.-Gen. Sir A. T., K.C.B., C.M.G., Hon. Surg. to the King.

#### ROYAL FIELD ARTILLERY.

Bailey, Surg.-Maj. F. W., D.S.O.

Peck, Surg.-Maj. E. G.

#### ARMY MEDICAL SERVICE.

Alexander, Lt.-Col. (temp. Col.) J. D., R.A.M.C.

Barefoot, Col. G. H., C.M.G.; Bewley, Col. A. W.; Blackham, Lt.-Col. (temp. Col.) R. J., C.I.E., R.A.M.C.; Bliss, Lt.-Col. (temp. Col.) H. W., R.A.M.C.; Bowen, Lt.-Col. (temp. Col.) A. W. N., R.A.M.C.; Brazier-Creagh, Lt.-Col. (temp. Col.) G. W., C.M.G., ret. pay; Browne, Col. E. G. C., Browne, Maj. C. G., D.S.O., R.A.M.C.; Buswell, Lt.-Col. (temp. Col.) F. R., R.A.M.C.

Chopping, Lt.-Col. A., C.M.G., R.A.M.C.; Conway, Maj. J. M. H., R.A.M.C.; Cree, Col. G., C.M.G.

De Wesselow, Temp. Capt. O. L. V.; Daly, Col. T.; Dowsett, Lt.-Col. (temp. Col.) E. B., R.A.M.C.

Emerson, Maj. H. H. A., R.A.M.C.; Ensor, Bt. Col. and Lt.-Col. (temp. Col.) H., D.S.O., R.A.M.C.; Evans, Lt.-Col. (temp. Col.) P., C.M.G., R.A.M.C.

Fawcett, Lt.-Col. H. B., C.M.G., R.A.M.C.; Ferguson, Lt.-Col. (temp. Col.) J. D., D.S.O.; Furnivall, Maj. C. H., R.A.M.C.

Garrard, Col. J. J.; Gray, Col. W. L.; Greig, Lt.-Col. (temp. Col.) F. J., Res. of Off.

Harty, Maj. (temp. Lt.-Col.) T. E., R.A.M.C.; Hime, Lt.-Col. H. C. R., R.A.M.C.; Hinge, Lt.-Col. (temp. Col.) H. A., C.M.G., R.A.M.C.; Hooper, Lt.-Col. (temp. Col.) A. W., C.M.G., D.S.O.

Ievers, Maj. O., R.A.M.C.; Irwin, Col. (temp. Surg.-Gen.) J. M., Logar, Capt. D. D., R.A.M.C.; Luther, Col. A. J.

Macdonald, Col. S., C.M.G.; Macleod, Col. R. L. B.; Martin, Maj. C. J., R.A.M.C.; Martin, Maj. J. F., C.M.G., R.A.M.C.; Maughan, Maj. J. St. A., R.A.M.C.; Millar, Maj. C. R., R.A.M.C.; Morgan, Col. F. J.

Newland, Col. F. R.; O'Keefe, Surg.-Gen. M. W., C.B.

Pike, Col. (temp. Surg.-Gen.) W. W., C.M.G., D.S.O.; Pocock, Col. H. I.; Poe, Lt.-Col. (temp. Col.) J., D.S.O., R.A.M.C.; Pollock, Lt.-Col. (temp. Col.) C. B., R.A.M.C.; Profet, Lt.-Col. (temp. Col.) C. W., R.A.M.C.; Prynne, Lt.-Col. (temp. Col.) H. V., R.A.M.C.; Purser, Maj. L. M.

Roch, Lt.-Col. H. S., R.A.M.C.; Ryan, Maj. (temp. Lt.-Col.) B., D.S.O.

Scott, Col. B. H.; Scott, Temp. Capt. B., R.A.M.C.; Scott, Capt. T. H., M.C., R.A.M.C.; Shanahan, Lt.-Col. (temp. Col.) D. D., R.A.M.C.; Sheehan, Maj. G. F., R.A.M.C.; Sherren, Maj. H. G., R.A.M.C.; Silver, Lt.-Col. (temp. Col.) J. P., R.A.M.C.; Skinner, Col. B. M., C.M.G., M.V.O.; Slayter, Lt.-Col. (temp. Col.) B. W., C.M.G., R.A.M.C.; Symons, Lt.-Col. (temp. Col.) F. A., D.S.O., R.A.M.C.

Thomson, Maj. C. G.; Thomson, Col. J.; Thurston, Col. H. S., C.M.G., R.A.M.C.; Thurston, Maj. L. V., R.A.M.C.  
Whaite, Col. T. du B.; Woodley, Maj. R. N., R.A.M.C.; Wright, Col. R. W.

## CONSULTANTS.

Bowlby, Lt.-Col. (temp. Surg.-Gen.) Sir A. A., Knt., K.C.M.G., K.C.V.O., 1st Lond. Gen. Hosp., R.A.M.C.  
Fowler, Lt.-Col. (temp. Col.) Sir J. K., K.C.V.O., 3rd Lond. Gen. Hosp., R.A.M.C.  
Galloway, Maj. (temp. Col.) J., 4th Lond. Gen. Hosp., R.A.M.C.  
Gray, Maj. (temp. Col.) H. McL. W., C.B., 1st Scottish Gen. Hosp., R.A.M.C.  
Herringham, Lt.-Col. (temp. Col.) Sir W. P., Knt., C.B., 1st Lond. Gen. Hosp., R.A.M.C.  
Holmes, Temp. Lt.-Col. G. M.  
Eighty, Capt. (temp. Col.) H. M., 2nd Lond. Gen. Hosp., R.A.M.C.  
Sargent, Temp. Col. P. W. G., R.A.M.C.  
Sinclair, Temp. Col. T.  
Smith, Capt. (temp. Col.) S. M., 3rd Lond. Gen. Hosp., R.A.M.C.

## SOUTH AFRICAN CONTINGENT.

Lawrie, Temp. Capt. M. B.; Pringle, Temp. Maj. R. N.; Welsh, Temp. Capt. T.

## INDIAN MEDICAL SERVICE.

Manifold, Col. C. C., C.B.

## THE EMPLOYMENT OF AMERICAN DOCTORS.

Publicity has recently been given in the daily press to the statement that young American doctors have volunteered their services and will be freely substituted for British doctors in the hospitals of this country in order to set free the present medical officers of military age for active service abroad. A recent statement in an American journal that the Director-General of our Army Medical Service had asked for the supply of a hundred or more young American doctors has, we believe, not been contradicted, and may therefore be taken as the policy of the Army Medical Department. To them will be allotted posts in military hospitals in this country which they can fill without possessing either a commission or a qualification registrable here. A corresponding number of British doctors of military age holding commissions will thus be set free. So far, then, as military occupation goes, the accounts in the daily press have been based upon fact, if misleading in detail. As regards civilian practice, as far as we know, the question of the employment of American doctors has not arisen in any practical form. The legal obligations of the civilian practitioner, both in hospital and private practice, prevent the employment here of those whose names do not appear on the British Medical Register. So long as the present absence of reciprocity between the United States and this country in medical matters remains unrectified, registration implies the obtaining in this country of a medical diploma recognised by the General Medical Council.

## NEW RED CROSS HOSPITAL FOR GLOUCESTER.—

The Bishop of Gloucester's Palace at Gloucester has been fitted up as a Red Cross hospital. It will accommodate 100 patients, contains an X ray apparatus, and a complete electrical massage installation.

## OBITUARY OF THE WAR.

NORMAN ERNEST JASPER HARDING, M.B.,  
CH.B. EDIN.,  
MAJOR, ROYAL ARMY MEDICAL CORPS.

Major N. E. J. Harding, who died of cholera at Colaba Military Hospital on August 10th last while in command of a stationary hospital at Bombay, was 41 years of age. He studied at Edinburgh and at University College,

Liverpool, graduating in medicine at Edinburgh University in 1900, and entering the Royal Army Medical Corps a year later, after taking a diploma in Public Health. He obtained his captaincy in 1906, and his majority in 1914. He was seriously wounded in the Boer War, and for his services at that time was decorated with the Queen's medal with two clasps and the King's medal. He went to France with No. 12 General Hospital on the outbreak of war, and served there for 15

months, before taking to India the unit which he was commanding at the time of his death. Previously to the outbreak of war he had served in Burma and on the West Coast of Africa. He contributed an article on the Value of Koch's Treatment of Malaria, to the *Journal of the Royal Army Medical Corps*, and other articles of a historical and professional character.

In 1908 Major Harding married Dorothy, oldest daughter of the late Ernest Wetton, of Maidstone, and of Kobe, Japan.

ROGER FORREST HUGHES, B.A., M.B., CH.M. SYDNEY,  
CAPTAIN, AUSTRALIAN ARMY MEDICAL CORPS.

Captain R. F. Hughes, who was killed on active service on Dec. 11th last, was 26 years of age and the elder son of Sir Thomas Hughes, who was for many years Lord Mayor of Sydney. He was educated at St. Ignatius College, Sydney, entering the Sydney University, where he first graduated in arts, and obtained his medical qualifications at the end

of 1915. He then filled the position of resident medical officer at St. Vincent's Hospital until March, 1916, when he enlisted in the Australian Army Medical Corps. After serving for six months at a base military hospital in Sydney he was detailed for service as regimental medical officer to an Australian battalion in France, arriving there early in December. Ten days later while dressing a wounded man in his advanced station he was severely wounded and died the same

day. Captain Hughes was well known in athletic circles in Sydney. He represented his school at cricket and football and his university at hockey. Just prior to leaving Australia he married Eileen, youngest daughter of M. E. Maher, of Collaroy Station, Merriwa, N.S.W., with whom and his parents much sympathy will be felt for his untimely death at the outset of a promising career.

CHARLES KENNETH MCKERROW, M.A., M.B.,  
B.C. CAMB.,  
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain C. K. McKerrow, who died of wounds received the same day, on Dec. 20th last, at the age of 33, was elder son of the late Dr. George McKerrow, of Ayr. He was educated at Cargilfield and Charterhouse Schools, gaining from the latter the Science Scholarship of his year for Cambridge, and later an open scholarship at Clare College. He took a first class in science, graduated M.B. and B.C. in 1908, obtaining in the same year the diploma of the Conjoint Board. After holding resident posts at St. George's Hospital and being extern to the 1st Frauenklinik in Vienna, he joined his father in practice in Ayr for some years. On obtaining a commission in the R.A.M.C. in June, 1915, he was appointed regimental medical officer to a battalion of Northumberland Fusiliers, going with them to France, where he remained until his death.

Captain McKerrow was not one-sided in his development. At school and later he had some reputation as a middle-weight boxer, and he also played Association football for his college. His superior officer writes of him: "A few days before his death Captain McKerrow read an excellent paper on Trench Fever before our Divisional Medical Society, giving proof of his careful clinical work even in the trenches. I formed a very high opinion of him both as a gallant soldier and a skilful surgeon. He was absolutely fearless in the performance of his duty."

In January, 1915, Captain McKerrow married Jean, only daughter of the late James Craik, and leaves a widow and one son.

CLIFFORD CRAWSHAW PICKLES, M.R.C.S. ENG.,  
D.P.H. LEEDS,  
LATE CAPTAIN, ROYAL ARMY MEDICAL CORPS (T.F.).

Mr. C. C. Pickles, who died on Dec. 22nd last, after being invalidated out of the Royal Army Medical Corps, was 30 years of age, and the third son of Dr. J. J. Pickles, of Camp-road, Leeds, of whose six sons five were members of the medical profession and one a student before the war. Educated at the Leeds Grammar School, Clifford Pickles entered the School of Medicine at the University of Leeds, obtaining in 1909 the Conjoint Board qualification, and two years later the Public Health diploma of his University. After holding resident appointments at Leeds and acting as assistant in general practice at Harrogate and Ossett he was appointed

medical inspector of school children under the North Riding Education Committee and was stationed at Malton, where he was also in charge of the local company of the 5th Yorkshire Territorials. At the outbreak of hostilities he was medical officer at Gateforth Sanatorium, near Selby, and on mobilisation served with the 5th Yorkshire Regiment at home for some months, after which he was transferred to the medical service as a captain. He went out to France in

April, 1915, in charge of a clearing station, came home three months later with severe shell shock, and was invalided out of the service in October, 1915. In spite of his poor health he then took over the practice at Earby of his brother, the late Surgeon P. D. Pickles, who died of gas poisoning after going down with H.M.S. *Russell* in the Mediterranean last year. Unfortunately, his health did not improve, and an attack of broncho-pneumonia following influenza proved fatal.

Captain C. C. Pickles's service to his country was undertaken with no thought of himself. His transference from combatant to medical service was made at a time when doctors were urgently required for the Army, and the strain of his work contributed to the illness from which he never quite recovered. His record and that of his family are a notable achievement. Captain Pickles married in June of last year Dorothy B. E. Wilkinson, only daughter of Charles Wilkinson, of Boston Spa and Leeds.

#### THE FIRST BRITISH RED CROSS UNIT IN ITALY.

We have received from Dr. G. S. Brock, chief medical officer to the unit, a report of the first year's hospital work drawn up for the Joint War Committee, from which we take the following :—

Villa Trento, the headquarters of the ambulance unit, is on the high road beyond the bridge over the river Natisone at Manzanol, and within a dozen miles of the fighting on the Isonzo front, on Monte Sabotinò, at Oslavia, and on Monte Podgora. The villa is a large building of seventeenth century design, belonging to the Conte di Trento, with a central portion of three storeys and wings of two storeys, flanked on either side by tall pine trees. Behind the latter, on one hand, is a line of offices occupied by a detachment of Carabinieri, while on the other is a long building of which the upper storey, ordinarily used as a granary, now forms an important part of the hospital. There is plenty of garden space where convalescents can take air and exercise enjoyably.

Dr. Brock tells us that at the time of the unit's arrival (Sept. 5th, 1915) the villa was occupied as an Italian hospital and the first ambulance work consisted in transporting some 50 patients to the neighbouring Abbazia Hospital. Much had then to be done both in improving the very bad sanitary conditions and in adapting the villa to its purpose. This work, performed almost entirely by members of the unit, was speedily carried out. On Sept. 12th was received the first batch of 8 patients, and by the end of the month the number accommodated was 55. After dealing with defective sanitation the unit turned its attention to getting a satisfactory water-supply. Water from a deep well was found by Captain Franchini, of the VI. Army Corps, to be quite free from pathogenic organisms. A second source from an open stream, in spite of filtering, was impure, but no doubt often found its way into the unit's food and drink. Fortunately another source became available from the Acquedotto Poiano by the kind help of Colonel Moreno, of the "Genio" of the Army Corps, to which the unit is attached. This water is of excellent quality and practically unvarying quantity, is moderately soft, and under high pressure. The effect of this new water-supply on the health of the unit was immediate, there being no longer cases of diarrhoea. The absence of heating arrangements did not lead to serious inconvenience during the summer, but on the approach of cold weather something had to be done. The Genio provided stoves for all the wards and also for some of the rooms. By means of these and a number of petroleum stoves the villa has been fairly well heated. The villa is lighted by its own electric installation of gas-engine accumulators. The laundry arrangements were totally inadequate. Application was made to General Cavicchia, of the Direzione di Sanità of the 2nd Army, laying before him a scheme for the erection of a disinfecting-room, washhouse, ironing-room, and drying-room, which he very kindly had carried out by the Genio, and also provided a steam disinfecter and a complete set of apparatus, consisting of two large galvanised-iron boilers, a soaking tank, and a rinsing machine. Regarding the disposal of refuse, all combustible materials are burnt by two incinerators—one of brick built by the unit, the other of iron supplied by the Direzione di Sanità. Non-combustible materials are buried in a neighbouring field.

The original idea in the minds of the organisers of the ambulance unit, Dr. Brock tells us, was to provide as an adjunct to it a small evacuation hospital of 25 beds with 25 stretchers for cases requiring to remain in the hospital for a few hours only. The accommodation, however, has been gradually so greatly extended that 97 patients can now be provided with beds, and there is room in an emergency for more. The unit's funds do not at present allow of filling more than about 65 of these, and this may be considered for the moment the normal number. The ground floor of the villa was appropriated, as far as possible, for hospital purposes. The outbreak of Asiatic cholera made it necessary to prepare an isolation ward. A part of the granary was partitioned off into two rooms, one for suspected cases and the other for cases such as typhus or cholera. After the great battle in the first week of November, 1915, a great rush of wounded came from the Gorizia section. All the beds (54) in the villa were quickly filled and the remainder of the patients were put on mattresses or on straw in the granary in four long lines. As many as 150 patients were at one time in the hospital. The remaining part of the granary has since been partitioned off and divided into two, so as to form two large wards.

An out-patient department has also become a necessity. Many soldiers sent from the front into reserve are encamped in this neighbourhood, often unaccompanied by a medical officer. In case of illness they usually come for advice to this hospital. The number of these soon necessitated an out-patient department. A waiting-room and consulting-room have been partitioned off in the granary, and this work is undertaken by an Italian colleague, Lieutenant De Lisi, who has been attached to the unit from the first and has rendered invaluable assistance.

The pharmacy of the hospital is under the care of Lieutenant Balotta, another Italian officer detailed by the Direzione di Sanità to assist the unit. A certain amount of the drugs used has come from England, but the greater part of the pharmacy supplies is obtained from the "Magazzino Avanzato" of Udine. These are used not only for the hospital, but also for the out-patients. A certain equipment (hospital supplies other than drugs) was brought out from England and more followed later by sea. But a great many things had to be obtained locally, as, for instance, the furniture of the operating-room. Fortunately a large number of bales containing such stores, collected by the Ladies' Committee in England and Scotland, were sent with members of the unit coming out in time for the great rush of wounded. Since then the hospital has received many generous contributions of money and supplies from friends in Britain and from British residents in Italy. Large consignments have been received from various war hospital supply depots, including those of Kensington, Belgravia, Norwich, and Rome, and a very large one has now arrived from the Scottish Red Cross.

When the hospital was opened in September, 1915, the unit expected to act only as a clearing station. Later, according to instructions received from Colonel Moreno in regard to the stay of wounded in the hospital, the unit was to work only as a field hospital. It was soon realised, however, that when little fighting was in progress the work done might be that of a small base hospital, but when a rush of wounded is anticipated all the sick and wounded who can be safely transported are evacuated in order once more to take on the rôle of a field hospital.

The medical staff consists of the chief medical officer, who is also its "direttore," and two surgeons. The present chief medical officer has been with the unit since its work began. The two surgeons, Dr. W. E. Thompson, and Dr. W. A. Propert, joined later—in October, 1915—when Dr. W. R. Dakin and Professor Henry Tonks, F.R.C.S., the well-known artist, who had come out with the unit, were obliged to leave by other engagements. Mr. R. Creasy, of Windlesham, Surrey, took duty for a month at the beginning of 1916 in the absence of one of the surgeons. Dr. Propert rejoined some time ago. As to nursing, the unit at first went on as best it could with the help of men belonging to the unit and of some Italian soldier orderlies. Nineteen of the members, seven of them medical students, took duty as nurses and dressers. Eventually the authorities consented to female nurses being employed. The advent of female nurses made a vast difference for the better, many of them speaking Italian. Of our male nurses and dressers only five remain on the hospital side.

Up to the end of March, 1916, the numbers of patients treated were as follows :—

Consultations in out-patient department	...	1422
Total admitted to hospital up to March 31st	...	1022
" discharge "	...	967
In hospital on April 1st	...	55
Average number of days in hospital per patient	...	9·8
Total number of deaths	...	27
Deaths per cent. of patients admitted	...	2·6
" among sick only "	...	0·1
" wounded only "	...	4·5

The death-rate was thus very low considering the many severe cases. The only death among medical cases was in a case of double pneumonia. The 398 sick discharged were nearly all cured or convalescent. Among the few exceptions were eight cases of cholera removed to cholera hospitals on diagnosis, four terminating fatally. Cases of frozen feet with the skin apparently uninjured have been counted as medical, but those with the skin blistered or broken as surgical. The nature of the medical cases chiefly met with will be seen from the following table, relating to 450 sick admitted up to the end of March, 1916.

Disease.	Percentage to total sick.	Months of prevalence.
Frozen feet...	14·0	December, January, and February.
Gastro-enteritis (including gastritis and enteritis) ...	13·5	All months, but especially December and March.
Fever of influenzal type,	12·0	December and March.
" trench fever "	...	
Rheumatism, chronic and muscular...	9·0	All months.
Bronchitis ...	7·0	From November onwards.
Jaundice ...	6·0	January, February, and March.
Paratyphoid ...	3·8	From November onwards.
Pleurisy ...	2·9	From December onwards.
Otitis media ...	2·0	
Conjunctivitis ...	2·0	February and March.
Cholera ...	1·8	Nov. 9th to Dec. 7th.
Pneumonia ...	1·6	December, January, and February.

It is remarkable that no case of cholera occurred in members of the unit, many of whom were constantly coming in contact with cholera patients; this was no doubt the result of the precautions taken, including anti-cholera vaccinations of nearly all the members shortly after arrival with vaccine supplied by the Lister Institute of London. It is also striking to find true typhoid absent, as well as the comparatively large number (17) of paratyphoid cases. In the Italian Army antityphoid vaccination has been practised, but not anti-paratyphoid vaccination. A combined vaccine is, however, now being largely used containing 800 million typhoid and 500 million paratyphoid B bacilli per cubic centimetre, in three doses at intervals of a week, the last two doses of 1 c.c. being double the first. The paratyphoid was on the whole of a benign type and unaccompanied by grave complications. A great difference of opinion prevails as to the causation of " piedi congelati " (frozen feet). Dr. Brock is convinced that the puttee is the chief offender.

There have been a great many visitors, both Italian and English. The King of Italy has paid three visits, at the last one decorating the commandant, Mr. G. M. Trevelyan, with the silver medal for valour. Another royal visitor on three occasions was the Duchess of Aosta.

A report follows on the surgical cases in the hospital by Mr. W. E. Thompson, M.B., Ch.B. Edin. The numbers of surgical cases, he tells us, greatly varied. At the commencement wards had been prepared and an operating theatre reconstructed. Instruments in large variety, tables and cupboards of good sterilisable material were procured and a good supply of dressings was put ready to hand. It was soon found that more apparatus was needed, especially a bacteriological laboratory and an X ray installation. Both of these have since been sent, the microscope the gift of Miss Gray, of Rome. The other gift, the X ray installation, is largely owing to the generosity of Dr. Barbour, of Edinburgh, and Mr. Saunders, of Croydon. A great variety of surgical cases has been dealt with from cuts and bruises to severe head, chest, and abdominal injuries. Up to March 31st, 1916, there were 84 operations, 34 of these being major. Taking into account the severity of so many cases where the only object attainable was relief of suffering, the death-rate of operation cases was just over 10 per cent. and the total mortality of all surgical cases about 1·5 per cent. There were 21 amputations of the leg and arm—12 being of the leg. Four cases of traumatic empyema were operated

on, in one a piece of shrapnel being literally picked off the back of the heart. Practically every surgical case required drainage in some form, and some for a length of time. For gas gangrene nothing was found better than peroxide of hydrogen and eusol, followed by 5 per cent. saline. The best absorbent dressing for these cases was the sphagnum moss bags presented by Mr. O. W. Cathcart, of Edinburgh, and others. These were a great saving in dressings as well as an ideal dressing.

Two supplementary reports bring the figures up to the end of June and August respectively, and deal with the second year of work. During the three months April to June the total patients admitted increased from 1022 to 1492—792 sick, 700 wounded. Unfortunately on June 7th the unit lost Dr. Propert's services by his enforced return to England. For the month of August the admissions to hospital reached a high figure, especially in the early part during the great Italian offensive which resulted in the capture of Gorizia, when there was a daily average of 160 occupied beds. As may be easily imagined, the strain on organisation and personnel was very severe, since not only were the numbers sometimes double that for which the unit is normally equipped, but it had to play the rôle of a clearing hospital as well. Fortunately a great many wounds were light, many patients in a day or two being fit to return to their regiments. Great although the strain was, everything went on with wonderful smoothness and efficiency, calling forth praise both from the Italian military and sanitary authorities and from the Chief Commissioner of the British Red Cross for the Mediterranean, Sir Courtauld Thompson, who happened to be here during the most strenuous part of it.

#### THE PANEL COMMITTEE FOR THE COUNTY OF LONDON AND THE MOBILISATION OF THE MEDICAL PROFESSION.

The following resolutions were passed by the Panel Committee of the County of London at their meeting on Tuesday last, Jan. 9th :—

(a) That the Panel Committee are of opinion that, in respect to the proposal to mobilise the medical profession, it is essential, in order to secure the efficient working of any scheme adopted, that extended powers be conferred upon the Central Medical War Committee in connexion therewith, and that the personnel of the Committee be strengthened by the addition of at least six practitioners actively engaged in panel practice, one of whom should be a woman.

(b) That the Panel Committee are of opinion that, in so far as the recommendations of the Central Medical War Committee shall have reference to the services rendered by the medical profession to the civil population, if accepted, these should be carried into effect by a small executive committee appointed from the members of the Central Medical War Committee, with lay members appointed by the Director of National Service.

(c) That the Panel Committee are of opinion that the difficulties of these Committees in this connexion would be greatly lessened and a considerably increased number of medical men set free for active service abroad without serious interference with the medical needs of the civilian population if much greater use were in future made of the part-time services of civilian doctors for the treatment of sick and wounded soldiers whilst in hospitals and for other military duties in this country.

(d) That copies of the foregoing resolutions be forwarded to the Central Medical War Committee, the Director of National Service, and to the other Government Departments concerned.

We comment on these resolutions elsewhere.

**CONVALESCENT HOME IN CALCUTTA.**—An offer has been made and accepted from Calcutta to entertain 100 men and 10 or more officers invalided from Mesopotamia. Mr. Galstaun has given the use of his house in Circular-road, while Raja Kristo Das Law has lent No. 23 Theatre-road as a residential club for convalescent officers. The Calcutta nursing division of the St. John Ambulance Brigade are fitting out these two fine residences for the purposes they are to serve. The estimated cost of the furnishing and upkeep for five months has been put at 1½ lakhs of rupees, and this amount is likely to be forthcoming.

**METROPOLITAN ASYLUMS BOARD: THREATENED SHORTAGE OF AMBULANCES.**—The lack of motor and driver mechanics is reducing the ambulance service of the Asylums Board to a dangerous extent. The Ambulance Committee states that 37 per cent. of the ambulances are awaiting repair, and that probably within a few months the ambulance service will be unable to remove fever patients from their homes. The committee urges on the Board the necessity for the return of mechanics who have been taken for Army or munitions service.

## Obituary.

### THE SENATOR DE GIOVANNI.

OUR Rome correspondent writes:—After Grocco, Baccelli, and, after Baccelli, De Giovanni, the Tuscan, the Roman, and now the Venetian schools respectively have, in the year just closing, lost their most brilliant medical ornaments.

Born near Mantua on Sept. 27th, 1837, Achille De Giovanni began his medical studies in his native Lombardy, but, like so many of his compatriots, had to suspend them on the outbreak of the war against Austria. Serving under Garibaldi, whose commendation he earned in the fighting line, he re-entered the classes in 1860, the year of Lombardy's liberation, and threw himself into their work with an ardour which carried him with distinction through the curriculum till his graduation, with honours, in the final school. More than one University thereafter solicited and gained his services on its clinical staff, Pavia, Naples, and Padua especially, but in the last-named he found such acceptance that he never left it, and became from year to year the most popular and effective teacher on its medical professoriate. A consultant in much request throughout the kingdom, he was also a conspicuous figure at the medical congresses held annually in the leading cities, contributing to the transactions and debates papers on auscultation and percussion, on gout, on "dry arthritis," and on the pathology of the vena cava inferior, to enumerate some of his best known work. But in his later years State medicine became his absorbing interest, particularly in the field of tuberculosis, where he followed up a series of elaborate clinical investigations by others of a purely prophylactic tenor, till he was recognised as the inspiring spirit, and indeed as the initiator, of the "Lega Internazionale contro la Tubercolosi." His professional distinction and his public spirit won for him admission into the Senate of the kingdom, where he made his knowledge and his sagacity felt in many a debate on hygienic legislation. In private life he was austere even to stoicism, while essentially kind of heart and gracious in manner and address. His death, in its dramatic suddenness, was quite in keeping with the tenor of his life. He had opened the Medicus Annus of the Paduan school by a brilliant address on Monday, Dec. 4th, when, next day, he fell ill with cardiac symptoms supervening on the rheumatism to which he had long been a martyr, and in four days he succumbed. In both Houses of Parliament his death was put on record as a "national loss," while his Alma Mater, of which he had for four years been Rector Magnificus, suspended its functions, with the flag of Italy half-mast high.

## Medical News.

UNIVERSITY OF LONDON.—At the First Examination for Medical Degrees, held recently, the following candidates were successful:—

Frances Dacre Alexander and Eleanor Mary Ashmall, London (Royal Free Hospital) School of Medicine for Women; Frederick Bach, London Hospital; Ormonde Alan Baker, University College; Gladys Licha Buckley, Girton College; Dora Mahalah Cadman, London (Royal Free Hospital) School of Medicine for Women; Antoine Yves Cantin, London Hospital; Linda Catmull, Dorothy Spencer Chamberlain, Ivy Collier, and Annie Eveline Connan, London (Royal Free Hospital) School of Medicine for Women; Marguerite Ellaline Cooke, private study; Rustam Nusserwanji Cooper, University College; John Alexander Currie, Guy's Hospital (distinction in Physics); Percy Tyson Davidsen, Middlesex Hospital; Betty Dent, London (Royal Free Hospital) School of Medicine for Women; Conor John Donegan, St. Paul's School and St. Bartholomew's Hospital; Hilda Ray Dutton, University College, Exeter; Keridwen Valentine Edwards, University College, Cardiff; Lucy Margaret Esham, Victoria University of Manchester; Rueland Henry Evans, University College, Cardiff; Geoffrey Edward Woolcombe Felice, Guy's Hospital; Emmie Dorothy Fenwick, London (Royal Free Hospital) School of Medicine for Women; Olive Gwendolin Fisk, Girton College; William John Gale, B.Sc., Battersea Polytechnic S.W. Polytechnic, and private study; Mark Garden, London Hospital; Lena Bella Gayer and Geraldine Norah Geary, London (Royal Free Hospital) School of Medicine for Women; Brian Wilson Barnett Gordon, Epsom College and St. Mary's Hospital; Barnett Gould, S.A., London Hospital; Marjorie Pearl Christine Greene, Roedean School; Stanley Allwright Gunter, St. Bartholomew's Hospital; Frederick James Simkin Hall, University College, Reading; Gertrude Eleanor Harre, Girton College and London (Royal Free Hospital) School of Medicine for Women; Elizabeth Merriman

Heath, Marjorie Browning Hubert, and Irene Esther Kenworthy, London (Royal Free Hospital) School of Medicine for Women; Oscar Bevan Lean, Bootham School; Bessie Levin, University College; Denzil Haydn Lewis, St. Mary's Hospital; Ivor Lewis, University College, Cardiff; Muriel Jessie Lough, B.Sc., Birkbeck College; Mary Catherine Lynch, London (Royal Free Hospital) School of Medicine for Women; Ivan Bailey McCann, Guy's Hospital; Dorothy McNair, London (Royal Free Hospital) School of Medicine for Women; Edward Francis Malins, King Edward's High School, Birmingham; Harold Jordan Malkin, University College; Amin Mikhail, King's College; Emily Marjorie Milnes, London (Royal Free Hospital) School of Medicine for Women; Sybil Grace Moccatt, King's College and London Royal Free Hospital School of Medicine for Women (distinction in Inorganic Chemistry and in Physics); Leslie Stuart Morgan, St. Bartholomew's Hospital; Doris Maude Odium, B.A., London (Royal Free Hospital) School of Medicine for Women; Winifred Catherine Piggott, Bootham School, Bedford College, and London (Royal Free Hospital) School of Medicine for Women; Mary Winifred Pitt Lewis, Beatrice Myrtilla Powell, and Gwendolen Mary Pratt, London (Royal Free Hospital) School of Medicine for Women; Margaret Annette Quine, Victoria University of Manchester; John Grosscott Reed, Epsom College and St. Thomas's Hospital; James Stuart Ricketts, King's College; Edith Margaret Ross-Johnson, Newnham College; Effie Frederike Amelia Samter, Victoria University of Manchester; E. Virginia Saunders-Jacobs, B.Sc., Newnham College; Alfred Sonn, London Hospital; Christopher James Lewen Sharp, St. Paul's School; Thomas Archibald Shaw, Guy's Hospital and Mill Hill School; Abraham Isaac Silverman, Middlesex Hospital; Leonard Smalley, St. Thomas's Hospital; George Morris Stoker, Guy's Hospital; Edward Howard Strange, University College, Cardiff; William Hedley Summerskill, Guy's Hospital; Arthur Cleve Damian Telfer, St. Bartholomew's Hospital; Wenefride Thompson, London (Royal Free Hospital) School of Medicine for Women; Estlin Hugh Weatherall, St. Bartholomew's Hospital (distinction in Biology); Leslie Ralph Augustus Wells, Guy's Hospital; Enid Margaret Williams, Swansea Technical College and King's College; Trevor Morgan Raleigh Williams, Swansea Technical College and University College; Henry Norman Witham, St. Thomas's Hospital; and Jacob Elias Zeitlin, London Hospital.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At examinations held recently the following candidates were successful:—

#### FIRST PROFESSIONAL EXAMINATION.

*Chemistry and Physic.*—Barbour Dous, King's College; John Caradoc Evans, London Hospital; Barnett Goldfoot, St. Bartholomew's Hospital; Frank Guiver, London Hospital; Frederick Richard Hall, St. Thomas's Hospital; Stratford Smith Hewitt, St. Mary's Hospital; Archibald Louis Percy Jeffery, Merchant Taylors' School; Evan Thomas Lloyd, Guy's Hospital; Elizabeth Kathleen Mackay and Norah Katharine Priestley, London School of Medicine for Women; Isaac Rosenberg, Guy's Hospital; Hans Rundstrom, King's College; James Mortimer Schofield, St. Mary's Hospital; Joseph Stanley Thomas, London Hospital; William John Vickers, Birmingham University; and May Grant Williams, London School of Medicine for Women.

*Physics.*—Jose Roberto Azurdia, Liverpool University; Montague Hirsch Burks, London Hospital; Henry Thomas Chiswell, Guy's Hospital; Octavio de Felix Pedrosa, London Hospital; John Hurley Piddock, Birmingham University; Tewfik Yusif Suliman, King's College; and Donald Radcliffe Thompson, London Hospital.

*Chemistry.*—William Laing Dunlop and Edward Richard Hughes, Liverpool University; Joseph Sonenberg-Bergson, King's College; and Daisy Coutts Wallace, Birkbeck College.

*Biology.*—Douglas Robert Ainsworth, Manchester University; Samuel Edward Amos, St. Thomas's Hospital; Jose Roberto Azurdia and William Ryding Bennette, Liverpool University; Ernest Gower Bryant, Manchester University; Samuel Bacon Chambers, University College, Southampton; Leslie Charles Frederick Chevens, St. Thomas's Hospital; Abdallah Yakub Dowek, Manchester University; William Laing Dunlop, Liverpool University; John Caradoc Evans, London Hospital; Rihd Akhnoor Fanous, Manchester University; Leslie Joseph Gabe, Middlesex Hospital; John Burnall Gann, London Hospital; Stratford Smith Hewitt, St. Mary's Hospital; Janet Hughes, South Western Polytechnic; Gerald Israelsam, London Hospital; Frederick James, Charing Cross Hospital; Archibald Louis Percy Jeffery, Merchant Taylors' School; Eric John Llewellyn Jones-Evans, St. Thomas's Hospital; Harold James Lyon, Guy's Hospital; Elizabeth Kathleen Mackay, London School of Medicine for Women; Horace Abe Nathan, South Western Polytechnic; Hilda Margaret Neal, Royal Free Hospital; John Hurley Piddock, Birmingham University; Francis Louis Rayner and Isaac Rosenberg, Guy's Hospital; Hans Rundstrom, King's College; James Mortimer Schofield, St. Mary's Hospital; Edgar James Targett, Birmingham University; Joseph Stanley Thomas, London Hospital; William Henry Turner, Guy's Hospital; and Charles Henry White, Birmingham University.

#### SECOND PROFESSIONAL EXAMINATION.

*Anatomy and Physiology.*—John Harrison Allan, Liverpool University; George Wilfred Almeida, London Hospital; Douglas Albert Raoul Aufranc, Middlesex Hospital; John Binford Barnett, Birmingham University; Richard Alec Dudley Jefferson-Bernhardt, Middlesex Hospital; Sarah Aileen Florence Boyd-Mackay, London School of Medicine for Women; William Mark Brown, Guy's Hospital; Harris Cohen, University College, Cardiff; Hyman Solomon Cohen, London Hospital; Morris Cohen, Guy's Hospital; Cecil Gerald Segeley Corner, Madras Medical College; John Paul de Silva, London Hospital; Theodore Henry Dobrashian, University College; Keith Mitchell Keitley Duff, Guy's Hospital; Cecil Weldon Empey, London Hospital; Gwilym Pennant Evans, St. Mary's Hospital; James Fanring, London Hospital; Lucie Gaillard, Madras Medical College and King's College; William Bertram Hargreaves, Aberdeen and Manchester Universities; William George Hay, South African College and Guy's Hospital; Arthur

Robert Hill, Middlesex Hospital; Reginald Walter Patrick Hosford, St. Bartholomew's Hospital; Graydon Hume and Mahmoud Fahmy Ismail, Guy's Hospital; George Valentine Chapman Last, Liverpool University; Hyman Jacob Levy, University College, Cardiff, and St. Bartholomew's Hospital; Elisabeth Esther McColloch, Liverpool University; Ambali Krishna Menon, Madras Medical College, and London Hospital; Amin Mohamed Mishad, King's College; Eva Morton, London School of Medicine for Women; James Lucius Cumillo O'Flynn, University College, Cardiff, and St. Bartholomew's Hospital; Evan Albert Iris Phillips, University College; Leslie Penhall Phillips, Henry Chris'offers Powell, and Charles Nathaniel Reid, King's College; John Charles Ryder Richardson, London Hospital; Albert Ernest Sawday and Harry Norman Schapiro, Guy's Hospital; Campbell Shaw, St. Bartholomew's Hospital; Latif Abtalib Simtka, Cairo and St. Bartholomew's Hospital; Younis Ahmed Sunbul, St. Mary's Hospital; Beriah Melbourne Gwynne Thomas, University College, Cardiff; George Marston Trist, King's College; Alfred Douglas Weston, Middlesex Hospital; Gladys Mary Thurlow Williams, Cardiff, and Birmingham University; John Edward Wright, Guy's Hospital; Owen Waller James Wynne, Dublin, and King's College; and Alfred Ernest Young, Bristol University.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The second series of lectures on the Anatomy of the Human Body will be delivered by Professor Arthur Keith, Conservator of the Museum, for first-aid and ambulance students, at 5 P.M., in the theatre of the College in Lincoln's Inn Fields, on Mondays, Wednesdays, and Fridays, commencing on Monday next, Jan. 15th. Anatomical preparations and specimens, used for purposes of illustration, will be placed on exhibition in the theatre from 3 to 5 P.M. on each lecture day. On the following day the same preparations will be placed in the hall of the Museum, where they may be studied between the hours of 10 A.M. and 5 P.M.

At the Preliminary Science Examination for the Licence in Dental Surgery the following candidates were approved in the undermentioned subjects:—

*Chemistry and Physics.*—Reginald James Hooker, Municipal Technical College, Brighton; Elisha Clemens Kent, South African College; Philip Heygate Knowles, Rearing School; George Levy, Guy's Hospital; Peter John Morrison, South African College and Guy's Hospital; and George Edward Smith, Liverpool University. *Chemistry.*—Levi Austin Brown, University of North Wales, Bangor; and Gilbert James Burberry Rowe, Municipal College, Bournemouth. *Physics.*—Gerald Fraser Smith, Middlesex Hospital.

**ROYAL MEDICAL BENEVOLENT FUND.**—At a meeting of the committee held on Dec. 12th, 1916, 30 cases were considered, and £317 15s. granted to 28 of the applicants. The following is a summary of the cases relieved:—

**Widow, aged 44,** of M.B. Lond. who practised in London and died in August, 1916. Owing to the war it was impossible to sell the practice. Applicant lives in own house, which is to be sold, and when he affairs are settled her income will only be about £120 a year. Has two children, aged 8 and 9. Wants help towards the education of her son who is a candidate for Epsom, but not likely to be elected for over a year. Voted £5.—L.R.C.P. Eltin., married, who practised at Berwick. N.B. Owing to ill health his earnings have only been about £70 per annum for some time, and his wife, aged 70, is now blind, and a daughter who was a housekeeper has had to give up her post so as to be able to nurse her father and mother. Voted £21 in two instalments.—Daughter, aged 69, of M.R.C.S. Eng. who practised at Cambridge and died in 1897. Applicant was able to earn a living by taking in paying guests on the south-east coast until the war commenced, but since has not been successful, and has had to give up her house. Only income £35 per annum. Relieved once, £12. Voted £12 in 12 instalments.—Daughter, aged 70, of M.R.C.S. Eng. who practised in London and died in 1873. Applicant was a governess in Russia when the war commenced, and all her savings were in a Berlin bank. For the last two years has earned a living by clerical work, but her eyesight has now failed, and has had to give it up. Only income a pension of £30 from another charity. Relieved twice, £24. Voted £12 in 12 instalments.—Daughter, aged 59, of M.R.C.S. Eng. who practised in India and London and died in 1873. Applicant left unprovided for, and owing to ill-health unable to earn a living. Only income £2 per annum. Relieved three times, £22. Voted £10 in two instalments.—Daughter, aged 58, of M.R.C.S. Eng. who practised at Hammersmith and died in 1908. Owing to ill-health unable to work, and only income occasional help from friends and from the Guild. Relieved nine times, £122. Voted £18 in 12 instalments.—Widow, aged 59, of L.S.A. Lond. who practised at Bournemouth and died in 1913. Has endeavoured to earn a living by taking in lodgers, but since the war has been unsuccessful, and has only received £3 this year. Has received a gift of £26 from another society. Relieved twice, £24. Voted £12 in 12 instalments.—Daughter, aged 51, of M.R.C.S. Eng. who practised in London and died in 1891. Left without means and very delicate, and her small income has had to be expended on medical attention. Income £25 from another society. Relieved seven times, £74. Voted £10 in two instalments.—Daughter, aged 51, of M.R.C.S. Eng. who practised at Gillingham and died in 1914. Applicant left without means, her father having been an annuitant of the Fund for some years. Never trained to work and can only earn a few shillings a week in a domestic capacity. Relieved three times, £29. Voted £12 in 12 instalments.—Widow, aged 74, of M.R.C.S. Eng. who practised at Rye and died in 1891. Applicant's income is not more than £50 per annum, and she has cataract in both eyes. Her two daughters are married and unable to help her. Relieved once, £12. Voted £12 in 12 instalments.—Widow, aged 55, of M.R.C.S. Eng. who practised at Yelverton and died in 1908. Left without means and endeavours to make a living by taking in boarders, but is not successful. Her eyesight is bad. Relieved ten times, £119. Voted £12 in 12 instalments.—Daughters, aged 44, 51, and 55, of M.R.C.S. Eng. who practised at Bodmin and died in 1912. On the death of the father the life interest in an estate ceased, and the only certain income of the applicants is £5 each. Two suffer from bad sight and the other quite unable to work. Relieved once, £18. Voted £18 in 12 instalments jointly.—Daughter, aged 70, of M.D. Lond. who practised at Cheltenham and died in 1879.

Applicant was left without means and has always had fair health, and is now suffering from acute rheumatism. Only income £39 per year from another charity and a small annuity. Relieved three times, £36. Voted £12 in 12 instalments.—Widow, aged 43, of M.R.C.S. Eng. who practised in North Wales and died in 1910. Applicant was left without means and had two young children, now aged 10 and 7 years. Lives with her aged parents who are not well off, and can only provide a home. Relieved five times, £50. Voted £10 in two instalments.—Widow, aged 73, of L.S.A. Lond. who practised in Bermondsey and died in 1887. Applicant managed up to the commencement of the war by keeping a boarding house on the south-east coast, but has had to close it down, and is still responsible for various charges against the house. Two children who help as they can. Relieved once, £15. Voted £2 and referred to the Guild.—Widow, aged 52, of M.D. Dub. who practised at Widnes and died in 1915. Left totally unprovided for with three children, only one of whom is working. Applicant's health is very indifferent. Allowed to live rent free in a friend's house. Relieved once, £10. Voted £12 in 12 instalments.—Daughter, aged 55, of L.R.C.S. Glasg. who practised at Glasgow and died in 1883. Endeavours to earn a living by teaching music, but cannot obtain sufficient pupils. Only permanent income £25. Recommended by the Glasgow branch of the Guild. Relieved once, £12. Voted £12 in 12 instalments.—Widow, aged 58, of L.S.A. Lond. who practised at Limehouse and died in 1891. Applicant was left unprovided for with two young daughters, both of whom are now working, but only able to earn a little. Burns a little by needlework, but finds it difficult to meet expenses. Relieved nine times, £33. Voted £12 in 12 instalments.—Widow, aged 71, of M.D. Eltin. who practised at Cambridge and died in 1908. Applicant endeavours to make a living by taking in boarders, but is not successful. Friends provide £18 per annum. Relieved six times, £48. Voted £12 in 12 instalments.—Wife, aged 36, of M.B. Dub. who practised in various places in England and Ireland. Applicant had to leave him 18 months ago on account of his habits and cruelty. One child 12 years old. Applicant is a trained nurse, but unable to take permanent work on account of the child. Relieved once, £9. Voted £5 in two instalments.—Widow, aged 57, of L.S.A. Lond. who practised at Islington and died in 1905. Applicant left unprovided for with two sons, both of whom joined the Army; one was killed and the other is missing. Applicant is nearly blind, and health is very precarious. Relieved 12 times, £145. Voted £18 in 12 instalments.—Daughter, aged 64, of M.D. Eltin. who practised in London and died in 1873. Applicant has two sisters, and they endeavour to make a living by keeping a boarding house. The recent death of the mother has depleted the family income, as she has a pension which died with her, and the high cost of living makes it difficult to get on. Relieved once, £10. Voted £10.—Daughter, aged 60, of M.R.C.S. Eng. who practised at Yoxford and died in 1893. Has always had bad health, and two relatives who used to help her have died. Only income a pension of £29 from another society. Relieved eight times, £30. Voted £12 in 12 instalments.—Daughter, aged 59, of L.R.C.P. Lond. who practised at Brierley Hill and died in 1872. Has never been able to work through ill-health and has recently fractured her ankle. Only income a pension from another society of £25. Relieved nine times, £65. Voted £12 in 12 instalments.—Daughter, aged 43, of M.B. Eltin. who practised at Southampton and died in 1836. Applicant is a trained midwife, but owing to suffering from Bright's disease and heart trouble is unable to work. Only income 10s. 6d. per week allowed by friends. Relieved three times, £24. Voted £12 in 12 instalments.—Widow, aged 62, of L.R.C.P. Irel. who practised at Liverpool and died in 1885. Applicant earns a living by nursing, but owing to indifferent health and bad cough unable to obtain permanent work, and only earned £22 during the year. Relieved four times, £22. Voted £12 in 12 instalments.

The committee also granted special war-time Christmas gifts of £1 each to 150 annuitants and 120 grantees. Subscriptions may be sent to Dr. Samuel West, hon. treasurer, at 11, Chandos-street, Cavendish-square, London, W.

**THE KING HAS SANCTIONED THE FOLLOWING PROMOTIONS IN THE ORDER OF THE HOSPITAL OF ST. JOHN OF JERUSALEM IN ENGLAND:**—Colonel Sir John Rose Bradford, K.C.M.G., C.B., F.R.S., A.M.S.; Colonel Alfred Percy Blenkinsop, C.B., A.M.S.; Colonel Sinclair Westcott, C.B., C.M.G., A.M.S., and Surgeon-General John Chislet Culling, A.M.S., to be Knights of Grace; and Lieutenant-Colonel William Richard Blackwell, R.A.M.C., and Fleet-Surgeon Robert William Glennan Stewart, R.N., to be Esquires.

**ROYAL SOCIETY OF ARTS (JOHN-STREET, ADELPHI).**—Amongst the lectures announced for the coming session are the following:—W. A. M. Goode, honorary secretary of the National Committee, on "Relief Work in Belgium" (Jan. 24th); Dr. R. Fortescue Fox on "The Future of British Spas" (Feb. 7th); Lawrence Chubb, secretary of the Commons Preservation Society, on "High-ways and Footpaths." The time in each case is 4.30 P.M. Admission is by ticket.

**ROYAL SANITARY INSTITUTE.**—A discussion will take place on Wednesday, Jan. 31st, at 4.30 P.M., at 90, Buckingham Palace-road, on the physical welfare of children after infancy from the national, social, and public health standpoints. The debate will be opened by Dr. W. Leslie Mackenzie, medical member, Local Government Board for Scotland. The chair will be taken by Sir George Newman, chief medical officer, Board of Education.

**THE LATE SIR F. W. BORDEN.**—Frederick William Borden, who died last week in his seventieth year, came of medical parentage and was a medical graduate of Harvard, and entered the Canadian Army Medical Service as assistant surgeon to the 63rd Militia Regiment (King's County) in 1869. He rose to the rank of surgeon lieutenant-colonel and honorary colonel, and was made an honorary surgeon-general of the Imperial Army in 1911. He sat for 33 years in the Canadian Parliament.

## Appointments.

*Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

CORDINGLEY. GRACE, L.S.A., has been appointed Pathologist to the Venereal Diseases Department, Royal Free Hospital.  
DINNICK, O. T., M.R.C.S., L.R.C.P. Lond., Senior Assistant to the Venereal Diseases Department, Royal Free Hospital.  
GREEN, EDITH M. N., M.B., B.S. Lond., Senior Assistant to the Venereal Diseases Department, Royal Free Hospital.  
TOCKER, J., M.B., C.M., Medical Officer for the Morthooe District by the Barnstaple (Devon) Board of Guardians.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.*

## Notes, Short Comments, and Answers to Correspondents.

### HEALTH OF CEYLON.

A REPORT prepared by Mr. E. Sueter, Assistant Colonial Secretary, on the affairs of Ceylon for the year 1915, states that the estimated population of the island (exclusive of the military and shipping) is about 4,424,300, an increase of nearly 107,600 on that of the previous year, due to an excess of about 51,100 births over deaths and 56,000 arrivals over departures of Indian coolies. There are 113 males to every 100 females in the population of Ceylon. The birth-rate for the year was 37·0 per 1000 and the death-rate 25·0 per 1000, this latter being the lowest on record since 1898, when improved registration began, with the exception of the rate in 1904, when it was only 0·1 less. 171 infants under one year died to every 1000 born, against an average of 195. This rate is the lowest recorded during the preceding decennium. The proportion of deaths in the general community from certain principal causes to a million of the estimated population was as follows: Infantile convulsions, 2596; diarrhoea, 2465; bronchitis and pneumonia, 1146; putridis and other forms of tuberculosis, 952; dysentery, 774; ankylostomiasis, 468; malaria and malarial cachexia, 390; premature birth and congenital defects, 307; cancer, 92; enteric fever, 88; and small-pox, 35. Plague, which broke out in 1914 for the first time in the history of Ceylon, is still continuing, though the victims claimed in the year under review are very much less, as will be seen by the following record: Total cases in 1914, 413; ditto in 1915, 139; total deaths in 1914, 381; ditto in 1915, 128. On the other hand, and contrary to expectations, there was no diminution in the virulence of the disease, the total case mortality being 92 per cent., as in the previous year. 108 deaths per million were due to accidental drowning, 80 to falls from trees, and 53 to snake-bite; 342 deaths were attributed to homicide, against an average of 181. This corresponded to a rate of 77 per million—the highest ever recorded in Ceylon—and was due to the riots in June. The number of executions, too, rose to 76 from an average of 29, owing to the same cause.

There are 78 Government hospitals (in addition to the lunatic and leper asylums) equipped with modern hospital furniture and surgical appliances. The owners of estates have also provided 54 estate hospitals and 353 dispensaries. Four new hospitals are under construction. A general rebuilding scheme is in contemplation for the improvement of the Medical College. The full course of training for medical students is five years; a diploma in medicine, surgery, and midwifery (which can be registered in the United Kingdom) is granted to successful medical students. In Colombo there are a bacteriological institute, an ophthalmic hospital, a lying-in home, a hospital for women and children, and one for infectious diseases; there is also an establishment for the manufacture of calf lymph. The leper asylum, situated six miles from Colombo, contained 402 patients at the end of the year; the total treated during 1915 numbered 509. A smaller establishment for lepers exists at Kalmunai and has accommodation for 30, and it is now proposed to establish a leper colony at Mantivu in the Eastern Province.

The highest annual rainfall registered was at Garney Estate, Ratnapura, which had a total of 266·8 inches, and the lowest was at Mantota in Mannar, which had a total of 25·85. The annual rainfall at Colombo (Cinnamon Gardens) was 96·81 inches. The station showing the highest mean shade temperature for the year was Trincomalee with 84·4° F. and the lowest Nuwara Eliya with 60·7°. The figures for Colombo and Kandy were 81·0° and 77·1° respectively.

### STEAM-DISINFECTING APPARATUS.

We have received from the Grampian Engineering Company, Limited, of Stirling, N.B., and 43, Aldwych, London, W.C., an interesting brochure on "Modern Steam Disinfection," in which are described the "Velox" high-pressure steam and combined current-steam and vacuum-formalin disinfectors. The merits of these methods of physical disinfection are closely discussed and full illustrations of the various types of apparatus are given. Practical experiments are quoted demonstrating the sterilising efficiency of the machines.

T. B.—The statement was a definite and precise one and made as long ago as August 1st, 1916. In reply to a question by Mr. J. Anderson in the House of Commons, Mr. Forster stated as follows: "Instructions have been

issued to recruiting medical boards to ask each man definitely whether (a) he has been under treatment in a sanatorium; (b) his name has been notified to the sanitary authorities as suffering from consumption? No man whose answer to either of these questions in the affirmative will be taken into the Army, but it will obviously be necessary to verify his statements." Mr. Forster went on to add that the Local Government Board had arranged for local tuberculosis officers to supply particulars of all men of military age on the tuberculosis registers, and that these particulars would be supplied to the recruiting authorities with instructions that such men were not to be accepted for service. In cases of doubt the advice of tuberculosis officers was to be asked for.

N. K. M.—A special course on the diagnosis and treatment of venereal diseases is being held for London panel practitioners at the Rochester Row Military Hospital, S.W., and this is open to all medical men. Application should be made to Lieutenant-Colonel L. W. Harrison, R.A.M.C., at the hospital. Lectures have been announced at the London and Guy's Hospitals, and will doubtless be arranged at other metropolitan and provincial hospitals. Details will be given in our column devoted to control of venereal diseases. "A System of Syphilis" edited by D'Arcy Power and Murphy (Oxford Medical Publications, second edition, 1914. Five volumes. £2 2s.) is the most complete work in English on the subject. "A Manual of Venereal Diseases" (same publisher, second edition; 1913; 10s. 6d. net) is a practical volume. The Report of the Royal Commission on Venereal Diseases is a mine of information on the whole subject.

**ERRATUM.**—In the *Annus Medicus* in THE LANCET of Dec. 30th, 1916 (p. 1116), under the heading of "Army Medical Service," we referred to the duplication of the office of Director-General, and included the following phrase: "While Sir Alfred Keogh, who had been Director-General up to 1910, and who was in 1915 acting as Chief Commissioner for the British Red Cross Society in France and Belgium, became Director-General of the Army Medical Service at home." The year should have been stated as 1914 and not 1915.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

## Medical Diary for the ensuing Week.

### SOCIETIES.

#### ROYAL SOCIETY OF MEDICINE, 1, WIMPOLE-STREET, W.

##### MEETINGS OF SECTIONS.

Tuesday, Jan. 16th.

##### GENERAL MEETING OF FELLOWS: at 5 P.M.

Ballot for Election to the Fellowship.

Wednesday, Jan. 17th.

##### HISTORY OF MEDICINE (Hon. Secretaries—J. D. Rolleston, Charles Singer): at 5 P.M.

Exhibition of Books, Portraits, &c. (at 4.30 P.M.).

Paper:

Mr. R. R. Steele: A Medieval Panacea.

Thursday, Jan. 18th.

##### DERMATOLOGY (Hon. Secretaries—J. H. R. McDonagh, Henry MacCormac): at 5 P.M.

Cases (at 4.30 P.M.).

Friday, Jan. 19th.

##### ELECTRO-THERAPEUTICS (Hon. Secretaries—H. P. Cumberbatch, Robert Knox): at 8.30 P.M.

A CLINICAL EVENING will be held in the Electrical Department of St. Bartholomew's Hospital.

##### LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, LEICESTER-SQUARE, W.C.

TUESDAY.—4.30 P.M., Clinical Cases will be shown by Capt. W. Griffith, R.A.M.C., Dr. J. L. Bunch, Dr. W. K. Sibley, Dr. C. Kempster, and Dr. M. Dockrell. Paper:—Dr. O. Kempster: The Action of X Rays upon Diseases of Bacterial Origin.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

#### POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardo: Operations. Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

**FRIDAY.**—10 A.M., Dr. Simon: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

**SATURDAY.**—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE,** Prince of Wales's General Hospital, Tottenham, N.

**MONDAY.**—Clinics:—10.30 A.M., Surgical Out-patients (Mr. H. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. E. Whipham): Gynaecological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

**TUESDAY.**—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

**WEDNESDAY.**—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

**THURSDAY.**—2.30 P.M., Gynaecological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

**FRIDAY.**—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

**THE THROAT HOSPITAL,** Golden-square, W.

**MONDAY.**—5.15 P.M., Special Demonstration of Selected Cases.

**TUESDAY.**—5.15 P.M., Clinical Lecture.

**ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN,** 49, Leicester-square, W.C.

**THURSDAY.**—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Tuberculosis of the Skin and Lupus Erythematosus.

**ROYAL INSTITUTE OF PUBLIC HEALTH,** Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

**WEDNESDAY.**—4 P.M., Lecture I.:—Miss J. Lane-Claypon, M.D.: Principles of Organisation and Administration in Child Welfare Work. Lieut.-Gen. Sir Robert Baden-Powell, K.C.V.O., and Mr. F. J. Willis, C.B., have promised to take part in the discussion.

**ROYAL INSTITUTION OF GREAT BRITAIN,** Albemarle-street, Piccadilly, W.

**TUESDAY.**—3 P.M., Prof. C. S. Sherrington: The Old Brain and the New Brain, and their Meaning. (Lecture I.)

### EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners. Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C.

### MANAGER'S NOTICES.

#### VOLUMES AND CASES.

VOLUMES for the second half of the year 1916 will be ready shortly. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half-year's numbers (inland edition) are now ready. Cloth, gilt lettered, price 2s., by post 2s. 4d.

To be obtained on application to the Manager, accompanied by remittance.

#### ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

#### INLAND.

One Year	...	...	...	...	£1 10 0
Six Months	...	...	...	...	0 16 0

The Bradshaw Lecture

or

LAMINECTOMY IN GUNSHOT INJURIES  
OF THE SPINAL CORD.

Delivered before the Royal College of Surgeons of England on  
Dec. 15th, 1916,

BY COLONEL CHARTERS J. SYMONDS, C.B.,  
A.M.S., M.S. LOND., F.R.C.S. ENG.,

A VICE-PRESIDENT OF THE COLLEGE; CONSULTING SURGEON TO GUY'S  
HOSPITAL; CONSULTING SURGEON TO HIS MAJESTY'S FORCES.

MR. PRESIDENT, LADIES, AND GENTLEMEN.—Gunshot wounds of the spinal cord form one of the most fatal groups of battle injuries. It is stated that in the Spanish-American War the mortality was 75 per cent. higher than injuries of any other region of the body. According to Surgeon-General W. F. Stevenson, 58·3 per cent. of the cases in the Boer War died, and when there was actual lesion of the cord with fracture of the arch the death-rate was 75 per cent. Many die on the field, either from the injury to the cord in the cervical region or some associated injury when other parts in addition to the spine are hit. Of those who survive to reach the base hospitals, probably the majority succumb to the effects of renal infection within a few weeks; taking the cases admitted to one military hospital—Netley—in the five months beginning July 1st last, there were 28 deaths in 43 dorsal and lumbar cases.

Of those who escape early death, some remain helpless from paraplegia, with incontinence of urine and faeces, and sooner or later die from the effects of renal infection. A few, where the trunks of the cauda equina have been injured, recover more or less power in proportion to the immediate injury. Some of these recover control of the bladder and are able to shuffle about or walk a few miles with support. There are those who, beside the paralysis, suffer pain for many months, often to an unbearable degree. Only in the concussion cases of the cord itself does any complete recovery ensue.

My object to-day is to consider how far operative methods can bring relief in these distressing cases; whether the advances in diagnosis, in technique, and in the improved opportunities for operation have enabled us to ameliorate the fate of these men. Certain of the effects of gunshot injuries are altogether beyond our help; there are others where more or less benefit may result from operation; and there are not a few where operation may prevent the onset of serious complications.

The accounts given by Surgeon-General Stevenson and by Surgeon-General Sir G. H. Makins of the South African War are not encouraging; few operations were performed and little benefit was observed. Possibly the fear of aggravating the condition led surgeons to refrain from operation where some good might have resulted. On the other hand, unsuitable cases may have been submitted to operation which now would be left alone.

The function of the cord may be destroyed in the following ways by gunshot wounds. The missile—bullet or shell-fragment—may traverse and lacerate the structure, rendering recovery to a useful extent impossible. The bullet, on account of its high velocity, may produce by a concussion effect an acute necrosis of one or more segments without actually coming in contact with the cord. Fragments of the laminae may be driven in, producing laceration and compression. The missile may be lodged in the canal external to or within the theca and continue to exert injurious influences. Extravasated blood as a compressing force does not appear to have been encountered by Makins and others in the South African campaign, and I have not found compression from this cause in those operated upon by myself and others associated with me. Extravasation into the substance of the cord has been found, and as such is unreliable by any operation.

Of the foregoing conditions, indrawn bone fragments and lodged missiles may be removed by operation. The damage inflicted so far as the cord itself is concerned cannot be undone, nor can it be mended by any surgical means. The

most that can be expected of operation is that the removal of obvious sources of irritation and pressure places the parts in a better condition for recovery. In the cauda equina, where we have to deal with nerve trunks, capable, like peripheral nerves, of recovery from bruising, and of union with restoration of conductivity, surgery holds out a more hopeful prospect.

Gunshot injuries of the spine and cord fall, like wounds elsewhere, under two heads. First, the open septic wound with fracture of the spinous processes and laminae, associated with more or less injury to the cord; and secondly, the closed wound where sepsis is absent.

OPEN AND SUPPURATING WOUNDS.

Let us consider the treatment of the open septic wounds—in other words, of compound fractures of the spine. It would seem almost superfluous to insist upon the necessity of dealing with these cases on ordinary lines as soon as possible. The fact that a fair number requiring operation reach our home hospitals leads me to think that an operation on any kind of spinal injury is considered by many as one demanding special knowledge. This is true enough where the wound has closed and a full laminectomy is required, but in these septic wounds it is seldom necessary to remove any sound bone, and the undertaking can hardly be called a laminectomy.

In dealing with these septic wounds it is most important to keep to the track of the wound, enlarging in any direction sufficiently to obtain access to its deepest part; no formal incision should be made, and when the injury is unilateral the sound side should not be interfered with. My experience is somewhat limited, but I have not found it necessary to remove a sound lamina nor to interfere with the sound half of the arch. In a case under another surgeon, however, a lamina had to be removed to permit the extraction of a fragment of shell.

Should the dura mater be found punctured or cerebrospinal fluid escape no grave consequences need ensue. If the wound be treated by the open method meningitis is unlikely to occur. It may be necessary where the dura is widely lacerated to remove fragments of bone or metal from within the theca, and yet fatal meningitis may not occur. I am strongly of opinion that these wounds should be treated after careful irrigation by loose cyanide gauze packing, or by the salt pack if preferred, and left open. Excision and closure, I believe, more often fails than succeeds, except, perhaps, in the hands of a very few. In two recent operations communicated to me there was wide suppuration, followed by meningitis and death in one. The fatal issue not occurring till the sixteenth day suggests that free drainage from the first would probably have prevented this result, even though septic shell fragments had been removed from beneath the dura. (Case 1.)

It can never be necessary to open the dura in these cases if found uninjured. Blood has not been found in sufficient quantities to cause compression, and any thought of suture of the trunks of the cauda equina must be dismissed. If intrathecal pressure is suspected a lumbar puncture, if it can be made away from the wound, should give relief. In dealing with these wounds no difference should be made between complete transverse lesions and the partial injuries; all require attention.

I cannot refrain from taking the opportunity of condemning—as a result of a fairly wide experience—the practice of excising septic wounds. Within a few hours of infliction and in capable hands the method may succeed. Of the cases arriving in Malta from the Dardanelles and those now coming from France, in the majority the attempt has failed. I could relate many disasters in wounds of the head and soft parts, and all surgeons at the base hospitals at home must be familiar with the necessity of removing sutures, opening the wounds, and releasing confined pus. It is, I am convinced, a thoroughly bad practice, and, as more harm than good results, should, I think, be abandoned. From what I have seen I would make one exception only, and that is of head injuries. Where the wound is recent, practically free from infection, and the operator understands the method of aponeurotic flap-making, I have seen some splendid results, and one has only to read the accounts of Colonel Percy Sargent, Major A. J. Hull, and others to learn what can be done; but then we are not all such skilled workers or possessed with such sound judgment, nor all Harvey Cushing's.

From amongst some recent cases I select the following examples:—

CASE 1.—In a case operated upon 13 days after the injury a large septic fragment was found impacted in the canal, requiring the removal of an additional lamina for its extraction. Two smaller pieces were also found and removed. The cauda equina was much injured and cerebro-spinal fluid escaped. The wound was excised, sutured, and drained. Sixteen days later the patient died from meningitis.

In the judgment of those responsible for the treatment of this case it had been thought wiser to delay operation until the septic condition of the wound had been reduced. The wisdom of this course is open to question, so is the closure of the wound. Major Graham Simpson, who operated, and Lieutenant H. A. Wilson, under whose care the patient was admitted, both agree in this view. One other lesson is to be learnt from this case—viz., the resistance of the spinal meninges to infection. Here was a piece of shell, foul-smelling on removal from amongst the nerve roots of the cauda, where it had lain for 13 days, and yet there were no general signs of meningitis.

FIG. 1.

CASE 4.—Showing laceration of the cord by two small fragments of shell. A piece of khaki is seen filling the upper part of the gap.

CASE 3.—Another patient was not obtained for operation till 40 days after the injury. The evacuation of several suppurating foci in the muscles, and the removal of bone fragments lying on the dura gave immediate relief to the pain in the legs which had existed from the time of the injury, and had required the almost constant use of morphia.

CASE 4.—Captain H. W. Kaye has given me notes of the findings at an autopsy made five days after the infliction of the wound. The specimen before you and the drawing (Fig. 1) show the laceration of the cord, and the embedded portions of clothing, carried in by two very small metal fragments. The cause of death was suppurative meningitis. While no permanent good would have resulted from early operation, it was nevertheless the right thing to have done.

All these observations point to the necessity of early exploration of septic wounds in direct connexion with the

spine, keeping, as far as possible, to the infected area. It will seldom be necessary to remove more than the fragments of bone to relieve the pressure or reach the missile. Excision and closure where sepsis is established lead to wide suppuration and may determine a fatal issue. It is better to pack lightly with cyanide or iodoform gauze, or to dress with the salt pack.

#### CLOSED WOUNDS.

When the wound has closed and an aseptic operation can be carried out the question of the removal of bullets and shell fragments arises. In complete transverse lesion operation is only admissible for the relief of pain. A lodged bullet or fragment may cause untold misery. Removal may render the remaining weeks or months bearable. Operation wounds heal well, and respiratory difficulties if present can be met by local anaesthesia.

Where evidence of conductivity of the cord exists, is it necessary or wise in all cases to attempt removal of lodged missiles and bone fragments? If so, should this be done as soon as the wounds have closed, or should an interval be allowed to determine how far spontaneous recovery is possible? A lodged missile may be injurious in itself, as, for example, if it lies amongst the nerve trunks of the cauda equina or if it is pressing on a spinal nerve in the intervertebral foramen. On the other hand, the depressed fragments upon which the bullet lies may be doing harm. The bullet may have penetrated, fracturing and driving in the bone. Or, again, the bullet may have passed through the canal, entering by an intervertebral foramen and become lodged in the body of a vertebra where it is harmless. It may or may not have carried in a fragment of bone. These remarks apply chiefly where the missile enters from the back. Occasionally a shrapnel bullet may enter the vertebral body from the side, and beyond giving rise to symptoms of concussion may be quite harmless.

In considering the amount of benefit likely to arise from the removal of missiles and bone fragments, one at the outset must observe that the chief cause of the damage is the striking force. This cannot be undone; we can only, as stated earlier, by removing sources of possible irritation and pressure, promote the recovery of injured structures. It may be taken as the rule that when the missile enters from behind the arch is broken and fragments are driven inwards, whether it be lodged or not. Occasionally a bullet, usually a shrapnel, but in one case to be mentioned a rifle bullet, may enter through an intervertebral foramen, without carrying in bone fragments. It is important to recognise this fact of displacement, because the X rays do not always show the fragments.

If indrawn bone be left, what injurious effects may result? This question cannot be answered satisfactorily until we possess observations made some time after the injury. I am able to contribute one such observation to-day. (Case 8.) The specimen (Fig. 5) was removed nine weeks after the injury. It shows a fragment of bone embedded in the nerve trunks of the cauda equina. The bone surrounded by new material is closely adherent to the nerve roots. The appearances suggest a progressive irritation, which must have, had the patient survived, interfered with recovery.

Thorburn in his monograph describes a case where dense fibrous tissue was found embedding the nerve roots of the cauda. Major Soutar, of the Red Cross Hospital, Netley, has communicated to me particulars of a case where the fibrous tissue was so dense that he was obliged to abandon an attempt to free the nerve roots. In a case published in the *Journal of the American Medical Association* for April last a portion of a bullet was found surrounded by two solid scars. In five cases of suppurating wounds recently operated upon at Netley fragments of bone were in two removed from within the theca, and in three from the surface of this membrane. In one aseptic operation a bullet and fragments of bone were found pressing the theca to one side. In another instance fragments were successfully removed from within the sheath, together with a small piece of shell.

The answer, it seems to me, to the two questions I have just asked, is that operation should be undertaken when evidence of continuity of the cord exists, and that the sooner it can be done after the injury the better. One presumes that care will be taken to exclude cases of concussion, and that careful consideration will be given to the general condition.

The following cases illustrate the foregoing remarks:—

**CASE 5.** Removal of shrapnel bullet.—Private —, aged 29, was hit by a shrapnel bullet in the back on August 2nd, 1916, near Albert. Eight days later, on the 10th, he was admitted to the Royal Victoria Hospital, Netley, under the care of Captain Fergus Hewat, to whom I am indebted for the notes and the accurate account of the symptoms. There was an entrance wound over the eighth left interspace four inches from the posterior median line, but no exit wound. There was retention of urine and incontinence of faeces, no voluntary movement in the lower limbs, though muscular twitchings were seen at times and the legs were noticed to move unknown to the patient. There was reaction of degeneration in the muscles of the legs, but very slight in those of the thighs. The knee-jerks were absent; pin-prick sensation was lost on the front and outer aspects of both thighs; it was retained on the outer side of the legs and dorsum and soles of the feet, and in this last situation there was hyperesthesia. The scrotum retained sensation. X rays showed a shrapnel bullet slightly above and to the left side of the spinous process of the eleventh dorsal, with evidence of fracture of this vertebra. (Fig. 2.) After a few days the retention disappeared, a catheter being no longer required; the urine passed every five to ten minutes, accompanied by straining and some pain.

When I examined this patient before operation I found a spastic condition of the limbs. At times he was seized with severe pain in the legs, and cried out so much as to disturb the others. He had also abdominal pain with flatulence, and lay mostly on his side with the knees drawn up.

**Operation** (August 27th, 1916).—From the position of the bullet as shown by the X ray it might have been deeply buried in the bone. The symptoms pointed to a severe injury to the cord with progressive destruction, and not to a complete lesion. An incision was made in the median line and the muscles detached from the left side only. The bullet was found lying between the laminae of the eleventh and twelfth dorsal vertebrae. The eleventh lamina was broken, several fragments being driven into the canal. The spinous process and the right lamina, not being broken, were left. The opening into the canal was enlarged sufficiently to give a full examination and ascertain the absence of further fragments or of projecting bone. The dura was uninjured and was not opened. The muscles were sutured, the wound closed, and a primary union resulted. No immediate or striking result was observed after the operation, and only gradually did he obtain control over the bladder and rectum.

Three months after operation (Nov. 30th) his condition is as follows: He can retain urine for three hours, and longer during the night, and can, when the need comes, wait a little time. He has control over the rectum, but owing to the approximation of the thighs and tenderness in the back he cannot use a bed-pan, nor is he able to sit up on a commode. He has pain in both legs and below the ribs on both sides as well as in the abdomen. He is free from pain for several days at a stretch, and then may require a sedative for two or three nights. He can feel cotton-wool and pin-prick over the whole of the right lower limb, but not in the left thigh, while he can feel below the knee. He can move the toes and slightly the ankles on both sides, and he has some voluntary movement in the muscles of the thighs. For the most part, however, both lower limbs are in a spastic condition, the knees held tightly against one another.

It is impossible to say how far the recovery of voluntary power over the bladder and rectum has been due to the operation and not simply to the healing influence of time. The absence of any immediate effect and the very slow improvement suggest that the damage to the cord was due to the crashing effect and to the concussion and not to continued pressure. On the other hand, it must be remembered that the bullet with depressed fragments had lain on the cord for 25 days, and that already a spastic condition had set in, with pain which at times was most severe.

**CASE 6.** Removal of shell fragment from within the theca spinalis.—Sergeant —, aged 32, was wounded outside Trones Wood on July 31st, 1916. He was admitted to Netley on August 13th under the care of Captain G. F. Holt, to whom I am indebted for the notes. The patient had multiple wounds of the back, with flaccid paralysis of both legs. A week later, when I saw him, there was some power in the sartorius and adductors of the left thigh. The anaesthesia was irregular; the knee-jerks were absent. He had sensation of pins and needles in both feet and at times the legs jumped, especially when the bladder was full, and with these movements he had fresh pain. There were retention of urine and incontinence of faeces. The X rays showed a metal fragment directly in the shadow of the centre of the twelfth dorsal, with indefinite injury to the appendages of this vertebra. (Fig. 3.) The entrance wound

was to the left of the spinous process of the same vertebra.

**Operation** (August 26th, twenty-sixth day; wound healed).—As the missile had entered from the left the muscles were detached from this side only. A large collection of pus was encountered and the track led at once to the injured lamina. After removal of loose pieces of bone and some portions of the still firm lamina, an opening in the dura was found through which the cord could be seen. On separating the nerve trunks the piece of metal was removed from the front of the cord. No cerebro-spinal fluid escaped at this time or afterwards. The wound was lightly packed with gauze and granulated up. At no time was there any sign of meningitis.

Three months after operation this man is still in bed, the incontinence of urine remains, sensation has not increased in area, though it is more acute. The power in the adductors and sartorius muscles of the left thigh has increased; but there is no gain of power in the right lower limb. He has pain, at times severe, in both big toes, extending to the instep, but nothing to that existing before operation. There is no bed-sore.

No marked result can be directly traced to the removal of the foreign body, the general all-round improvement being such as one sees where a foreign body is not lodged. There can, however, be no doubt that his prospects of improvement have been increased by the operation.

As an example of the removal of a rifle bullet by a full laminectomy from amongst the nerve trunks of the cauda equina, the following case may be related:—

**CASE 7.** Corporal — was hit on Sept. 17th, 1916, and was admitted into Netley on the 27th under the care of Lieutenant S. G. Scott, to whom I am indebted for the notes. There was an entrance wound in the back six inches to the left of the median line opposite the level of the third lumbar vertebra, but no exit wound. The X rays showed a rifle bullet, base upwards, lying in the median line, the shadow being on the body of the first lumbar and partly over the disc below. Both legs were flaccid; sensation was retained in the right thigh, and he said he could feel the wound in the right calf. The left lower limb was completely anaesthetic. There was pain in both feet, particularly in the great toes. The only motor power was a just perceptible movement in the great toe of the right foot. There was severe cystitis with haematuria, and the man was ill and somewhat wasted. The symptoms indicated a lesion of the cauda equina, and operation was decided upon at once, it being arranged to control the urine through a suprapubic opening.

**Operation** (Oct. 1st).—The laminae and spinous processes of the first and second lumbar vertebrae were removed. The theca was found uninjured, and looked broadened opposite the first lumbar. The space between the theca and bony wall was searched in front of the cord, and the bullet not being found the theca was incised. On opening the dura a small elongated clot was found extending downwards. This was followed by removing the laminae of the third lumbar. Here the cauda equina was found much torn and bruised. On separating the nerve-trunks over the first lumbar the bullet was found lying in front of these structures with its base upwards. At this point the nerve-trunks were discoloured and torn. I was unable to trace the path of the bullet, but inferred that it had entered through the intervertebral foramen between the third and fourth lumbar, turned upon itself, and passed upward to the position where it was found. The theca and muscles were sutured with catgut, the wound closed by Michel's clips without drainage, and covered with a collodion dressing, primary union resulting.

The man improved rapidly in general health; the urine cleared far more quickly than with intermittent catheterism. The pain in the feet disappeared at once, and is now only felt occasionally in the left heel. At the present time, just under six weeks from the operation, he has gained power in the hamstrings and calf muscles, but there is no return in the extensor groups. Sensation has returned to a great extent in both lower limbs.

The rapid general improvement in this man must, I think, be set down primarily to the removal of the urinary sepsis. And this has promoted the recovery of the lesion in the cord. There is still incontinence of faeces. The bladder being still drained one cannot speak of the muscular power.

The possibility of an unnecessary search being made for a bullet lying in a harmless position is illustrated by the next case, for the notes of which I am indebted to Captain D. E. Shearer. The septic infection of the urinary tract, however, rendered any operation out of the question. The specimen shows that though the bullet may reach a position where it is in itself innocuous, the broken and displaced

bone may be doing harm. And here it must be noted that the X rays do not always show these depressed fragments. It may be said on the X ray findings that the bullet having injured the cord on its passage to a harmless position, and having done its work, operation will do no good. On the other hand, a fragment of bone may have been driven into the cord and be responsible for part of the symptoms, and, remaining, prove a continual source of local irritation and of pain, this more especially when the entrance wound is behind or to one side of the spine.

CASE 8.—Private — was hit by a shrapnel bullet which entered  $\frac{1}{2}$  inches to the left of the twelfth dorsal spinous process and was seen by the X rays to lie in the centre of the body of the eleventh dorsal vertebra. (Fig. 4.) No injury to the lamina was apparent. He was hit on Sept. 15th and admitted to Netley on the 29th with flaccid paralysis of both limbs. There was sensation down the front of the right thigh, shooting pains in the legs, and a feeling as of electric shocks in the left foot. The cystitis was severe, the sacral bed-sore moderate in size. There never was a moment when operation could be considered, for notwithstanding daily attention to the bladder, pus continued to escape, indicating infection of the ureters and kidneys; the temperature remained high, reaching sometimes  $103^{\circ}\text{F}$ . The wasting was extreme. The bed-sore improved under the careful attention of the nurses. He died just under nine weeks from the injury.

At the autopsy we found that the bullet had entered between the laminae of the twelfth dorsal and first lumbar on the left side. The upper border of the lower arch was roughened but not broken, so that from an external examination it did not appear that any fragment had been driven into the cord. On dividing the bodies from the arches (Fig. 5) the bullet was found almost completely buried in the body of the eleventh dorsal a little to the right of the median line. The exposed part was so small that it could not have exerted any pressure on the cord. The bullet in its course had broken off and driven in a fragment of bone, which was closely adherent to the trunks going to form the cauda equina. Just above this point the cord was softened and semi-fluid in its left half. Many of the trunks on the right side were apparently uninjured. The bladder was black from old blood effusion, but clean, the ureters much dilated and filled with pus, the pelvis of the kidneys in the same condition, and there were suppurating foci in the cortex.

Had the general condition permitted it an operation in this case would have done some good by removing the fragment of bone, the lesion being incomplete. The specimen and the drawing show the formation of cicatricial tissue round the fragment, the cause of the pain from which the man suffered. The damage to the cord was extensive and, of course, irrecoverable, yet one may take it that had it not been for the infection of the urinary tract this man would have lived indefinitely, and some benefit at least would have resulted from removal of the indrawn bone. The bullet could have been reached without difficulty by displacing the cord. Would its removal have been necessary? The question is worth asking, for similar cases will no doubt occur. Personally I do not think it is necessary to extract a bullet in this position. Exerting no compression, the only sound reason would be the danger of meningitis from infection. This had not occurred after nine weeks, and should not arise as a result of the operation, provided no attempt were made to remove it.

#### ~~X~~ INJURIES TO THE CAUDA EQUINA.

The spinal cord terminates, I may remind you, at the lower border of the first lumbar vertebra, the lumbar and sacral nerve roots occupying the rest of the canal. These, each composed of two trunks, the one motor the other sensory, pass to their respective foramina, where the bundles unite to form the composite nerve. The separation of the two parts of the nerve trunks explains many of the irregular paralytic and anaesthetic results of injury.

Gunshot wounds may pick out particular nerve trunks, and it is possible to ascertain with exactness which have suffered. The level of origin of each being known, it is also possible to reach the injured trunk after opening the theca. Unlike the cord, these intraspinal nerve trunks correspond in structure with peripheral nerves and possess a corresponding capacity for spontaneous recovery from bruising and partial laceration. If sutured they may be expected to unite with restoration of conductivity.

The diagnosis of these lesions does not present any difficulty when confined to the nerve trunks. In estimating, however, the prognosis, it is important and more difficult to

ascertain if there be any injury to the conus. Fortunately, recovery of power over the bladder and rectum usually occurs after a time. Pain in the legs and feet may be severe and last several months.

In a young soldier (Case 3) of 19, hit on July 1st, the pain in both legs was severe; it disappeared from the right after removal of fragments of bone and metal 41 days after the injury, but was still felt at times in the left after the lapse of six months, and was then severe enough to require morphia occasionally at night. Bladder control returned in six days after the injury in this case. He remains in his seventh month completely paralysed below the knees. The wound in this man was on admission large and septic and situated over the second and third lumbar vertebrae. For the notes of this case I am indebted to Captain Henderson.

In an earlier part of this lecture I have stated my own belief that early operation should be undertaken where foreign bodies are lodged in the arch of the vertebra or where a penetrating missile has broken the laminae. The reasons apply with greater force where pressure and irritation must, if existing, interfere with the recovery of injured nerve trunks. On the other hand, seeing the amount of spontaneous recovery that takes place in bruised or torn peripheral nerves, it is urged by many that a period of some months should elapse before any operation is undertaken on the cauda equina. So far as operation is limited to the removal of indrawn fragments and foreign bodies without opening of the theca I see no reason for delay, provided an aseptic operation can be performed.

The important question arising in this part of the cord is that of suture of the nerve trunks, for in this direction lies the future of the surgery of the cauda equina. Tuffier's successful case has shown the possibility of accomplishing this result. Should suture be attempted as early as possible, and at the same time as an operation for removal of bone fragments? Or is it better to make two operations, and, if so, is the second rendered more difficult by reason of the first? Again, should all operations be postponed for some months in these cases to see how far spontaneous recovery is possible, say for six months?

Past experience will lend support to delay, and so will the result of injuries to peripheral nerves. On the other hand, if full consideration be given to the findings recorded in late operations, and to the condition found at the autopsy in Case 8, the advantage from early operation becomes obvious. Here it must be remarked that sufficient time must be allowed to elapse for the exclusion of simple concussion. The wound also may take from one to three weeks to heal, so that there will always be a fair period for observation.

One's experience at present does not provide an answer to the question as to whether an operation for removal of fragments renders one for subsequent suture more difficult. Looking, however, to the amount of new bone formed in a case to be mentioned presently, one would surmise that the opening of the theca would be less difficult, for the earlier removal of fragments would diminish the osseous formation.

While recognising the magnitude of the operation, the difficulties of working in so confined a space, of finding and suturing the divided ends, and the danger of inflicting further injury, I believe it will be wiser to undertake operation as soon as all things are favourable. Unfortunately, in most of these cases arriving in England urinary infection and bedsores render operation impossible for many weeks. The prevention of urinary infection becomes a most important matter, and I hope, if time permit, to indicate a method by which this destructive complication may be met.

Cauda equina injuries have been comparatively common. I have notes of seven cases admitted into one hospital within six months. Though they all vary a good deal as to symptoms, there was no difficulty in recognising the lesion, and recovery was satisfactory up to a certain point. The following case is an example.

CASE 9.—In this case, under the care of Captain E. G. Smeed, there was complete flaccid paralysis, retention of urine, with incontinence of faeces. For many weeks the man's life was despaired of from urinary infection, septicaemia, and bedsores. He had double acute parotiditis and right panophthalmitis. At the end of  $1\frac{1}{2}$  years he is able to get about in a wheeled chair, and his general condition is excellent. There is complete paralysis of all muscles below the knees, those of the thigh being good. He can retain urine for three hours, while the rectal control is uncertain.

FIG. 2.

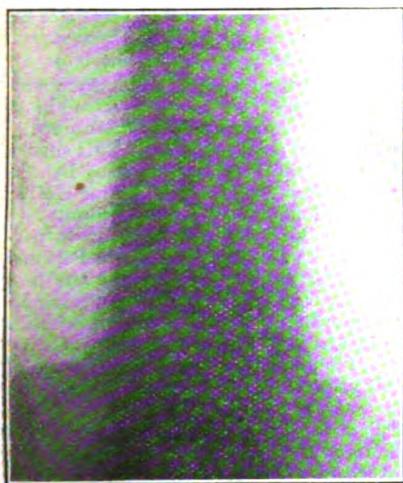

FIG. 3.

FIG. 4.

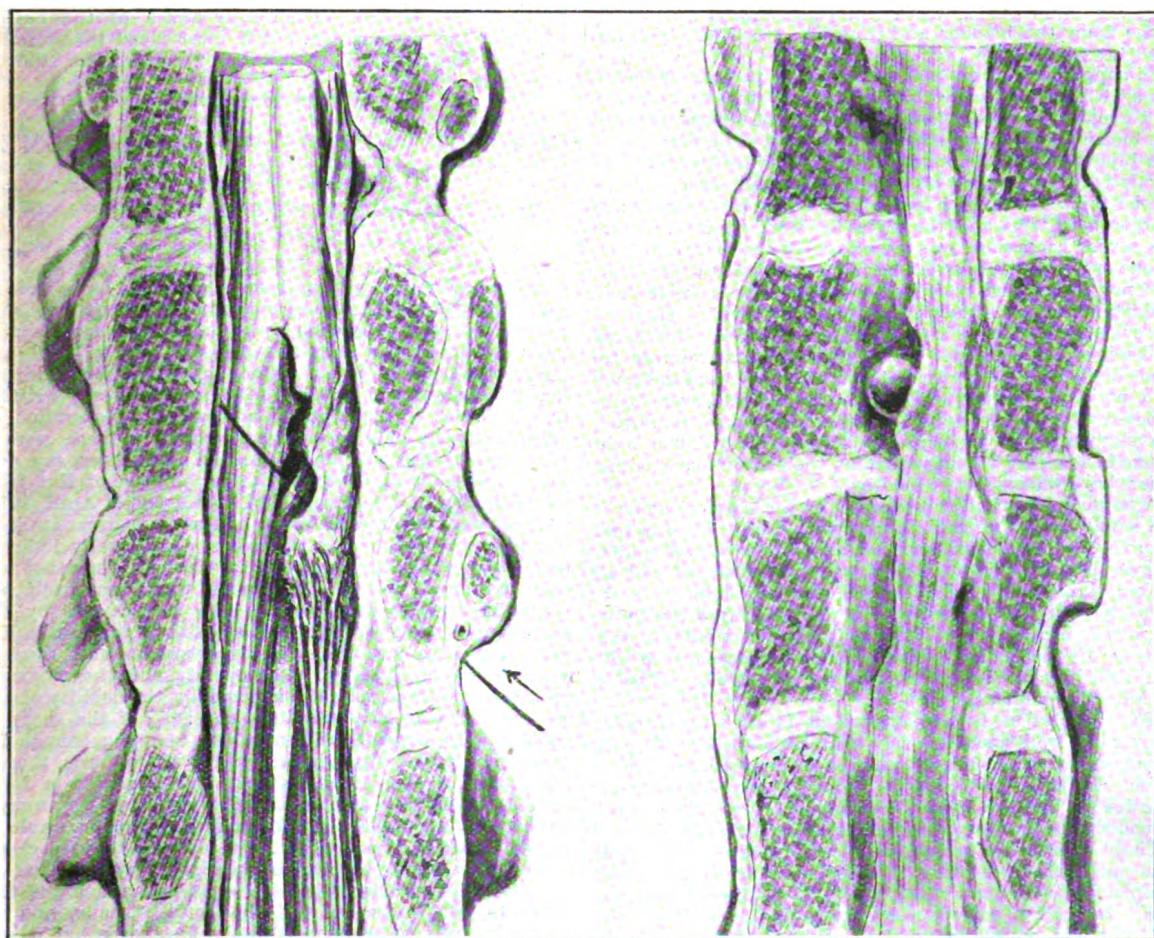

CASE 5.—Shrapnel bullet, with fracture of the left lamina of the eleventh dorsal vertebra.

CASE 6.—Shell fragment amongst the trunks of the cauda equina; level of twelfth dorsal vertebra.

CASE 8.—X ray showing position of shrapnel bullet.

FIG. 5.

CASE 8.—The bullet embedded in the posterior wall of the eleventh dorsal vertebra is made in the drawing to project too far. The irregular mass to which the nerve trunks are attached is the piece of indrawn bone. The course of the bullet and the laceration of the cord are also shown.

The bullet entered the ilium  $1\frac{1}{2}$  inches below the crest and passed through the fifth and fourth lumbar vertebrae. A sinus existed for more than a year, discharging small crumbs of bone from time to time. There is a marked enlargement from new bone formation about the fourth and fifth lumbar vertebrae.

While I have no doubt that, had the patient's condition permitted, an operation would have been wise soon after the injury, I have not sufficient experience to decide whether, after an interval of 18 months, an attempt to restore the continuity of the sacral nerves would be successful.

#### INJURIES TO THE CERVICAL SPINE.

My notes of ten recent cases, some from the Royal Victoria Hospital, others from the Welsh Hospital (the latter through the kindness of Lieutenant-Colonel Cook and his staff), together with several observed in Malta, show the remarkable tendency to recovery in those cervical injuries which reach our hospitals. In the higher lesions and those which are complete about the level of the fourth and fifth cervical vertebrae the patients either are killed outright or die early.

In one case a flat fragment of copper was embedded in the transverse process of the fourth cervical and was removed. There was considerable injury to the process and to that of the fifth, together with fracture of the bodies. Captain W. M. Howells, who made the X ray examination, thought there was probably a fracture dislocation.

CASE 10.—This young soldier (Private —) was wounded on Sept. 9th and lay in the open two days. He was admitted to Netley under Captain Newman Smith on the 17th with a septic wound in the neck behind the right sterno-mastoid; no exit wound. There was complete paraparesis of the right arm and leg with loss of sensation, partial loss of power of the left arm and leg with loss of sensation, retention of urine, and incontinence of faeces. The wound was opened up, drained, and the metal fragment removed. He survived three weeks, death being accelerated by haemorrhage from the bladder and from the track of a perineal drainage operation.

In none of the others was there any impaction of metal, though fragments were to be seen in the soft tissues. In three the X rays showed injury to the lateral mass of the fourth and fifth vertebrae or fifth only. In four others the injury was in the same region. All these patients had paraparesis of varying extent. In one the right arm and leg on the injured side, with loss of sensation on both sides; in another both arms and the right leg were affected. In all the severe cases there was retention of urine for a few days, in one only there was severe haemorrhage and cystitis. Time will not permit the record of the symptoms more than to indicate that the lesions were severe, as shown in eight by the evidence of paraparesis, &c., and in several by the X ray evidence of bone injury. One patient, the first referred to, died chiefly from haemorrhage from the bladder and the track of a perineal puncture. The cystitis, always severe, contributed to the fatal result. All the others have improved, the slighter cases rapidly, the severe slowly. The most severe is now just walking about at the end of four months, others have walked in two months.

A notable feature about wounds of the cervical spine is the small degree of cord injury when compared with that occurring in the dorsal and lumbar regions with a similar degree of bone injury. The transverse processes will be broken, a fragment of shell lodged and buried in the arch, even the body of the vertebra broken, and yet the nerve injuries be recoverable. The mobility and flexibility of this section of the spinal column, and in consequence the diminished resistance offered to the projectile, probably explains the difference.

The conclusion I have arrived at is that these cases recover so well spontaneously that unless there is pain from pressure on the nerve trunks it is wiser to leave them alone. In this view I may be wrong; it may be a sounder practice to remove loose fragments early, and a more extended experience may lead one to change this opinion.

Those who favour operation in cervical cases must admit that spontaneous recovery in many cases is so rapid and complete that too much may easily be attributed to operation. In such a case as that report by Major Hull<sup>1</sup> the recovery was unusually rapid, a definite improvement in sensation being observed the next day; and the patient had

recovered the use of his paralysed leg within three weeks. A depressed fragment of bone lying upon the theca was removed. It may certainly be admitted that the rapid healing of the wounds, the slight amount of shock, and the comparatively short duration of the operation justify more frequent resort to interference.

#### CONCLUSION.

With regard to the details of the operation of laminectomy I have nothing particular to say. They will be found most conveniently in Major Hull's "Surgery in War," where will also be read the best summary of recent progress. This should be amplified by reading the paper just referred to by the same author. I may add, however, that, unlike Major Hull's, my operations have been done under ether without any anxieties, but then we have had the advantage of a particularly skilled anaesthetist in Captain J. S. Steele-Perkins. One other point is worth referring to. Removal of the first lamina is the only difficulty, and can be met by applying an inch trephine after removal of the spinous processes. Trepanning the spine is, after all, the name used by Larrey and the older writers. I am indebted to Major Soutar, of the Red Cross Hospital at Netley, for this suggestion, and commend it to others.

I cannot claim, Mr. President, to have brought before you any brilliant successes or any new method. Rather is the attempt to deal with these distressing cases disappointing. I hope, however, in summarising a somewhat limited experience I may have indicated the comparative safety of laminectomy carried out under the best conditions, and emphasised the necessity of dealing promptly with septic compound fractures of the spine on ordinary lines, avoiding unnecessary incisions, removal of uninjured bone or opening the uninjured theca. The observations I have brought before you of the comparatively slight risk of meningitis in septic wounds when treated by the open method may, I hope, be of service. I am fully aware of the hurried nature of the composition, but I must plead the exacting nature of duties that have left but little time for study or investigation.

## GUNSHOT WOUNDS OF THE ABDOMEN DURING THE SIEGE OF KUT.

BY C. H. BARBER, M.R.C.S. ENG., L.R.C.P. LOND.,  
MAJOR, I.M.S.

SINCE my recent return from Bagdad I have had an opportunity of reading the several excellent papers published on the subject of penetrating wounds of the abdomen, notably those by Fraser and Bates in April last, and by Webb and Milligan in October. It is therefore now with some diffidence that I venture to add another to the number already written. But it seems to me that the advisability of operation on principle as the only reasonable treatment in these cases is still perhaps not sufficiently realised. Moreover, my own cases, practically all occurring during the siege of Kut from the beginning of December, 1915, to the end of April, 1916, were treated under exceptional and adverse circumstances. For instance, the wounds themselves were usually inflicted by a slower and larger bullet (about .400 inch) than that met with in Europe, so that the damage to the gut itself was presumably rather more severe than that caused by the smaller high-velocity missile. The health of the men in Kut grew progressively worse as the siege wore on, until towards the end one often hesitated to operate, and the prognosis after operation was seriously affected by the debility of the victims. The hospital buildings consisted of the shops or cubicles of a covered Arabian bazaar, each big enough for about four patients on the ground or two on beds, though beds were scarce. Besides these we occupied a large number of Arab houses, some of which had two storeys, but most of them were mud-brick dwellings comparable to Indian servants' quarters and very difficult to keep clean. Our fine new wooden hospital, with its large airy wards, which we had built just before the siege began, was almost the first thing to get in the way of the Turkish shells, and we had regretfully to abandon it in the first week, but it was almost a case of out of the frying-pan into the fire. The operating-room was also a mud-walled dungeon, with a large hole in the roof to admit light; in wet weather this

also admitted rain. To give proper nursing and suitable after-treatment was not easy, and the fact that the hospital was generally under shell- or bomb-fire once or twice a day did not add to the comfort or mental repose of its inmates. Such recoveries, therefore, as occurred after operation—and there were practically none apart from it—may be looked upon as the minimum number possible under this method of treatment; but to my mind they are sufficient to indicate the value of operation, and indeed to show that wounds of the abdomen involving the intestines should always be so treated. A further point of interest lies in the fact that owing to the small size of Kut and the proximity of the hospital to the trenches many of my cases were obtained within a few minutes to an hour of their being hit, so that they include a class of case which as a rule never reaches a hospital at all but dies on or near the field. Several of the cases were amongst soldiers or civilians who were hit in the town or on the river bank, close to the hospital, by snipers.

After South Africa the general impression left on surgeons' minds was that penetrating wounds of the abdomen involving the peritoneal cavity and its contents were best left alone, and indeed one excellent text-book went so far as to say that by this method 40 per cent. of cases recovered. But these figures, it is probable, are based on official records from admission- and discharge-books, in which gunshot wounds of the abdomen include all wounds, flesh or otherwise, in the abdominal region, and are useless for purposes of comparison. Makins saw no case recover in South Africa in which the small intestine was injured. Such operations as were performed were usually unsuccessful.

Laurent, from his experiences in the Balkan wars, preserved rather an open mind on the subject of the treatment of these wounds, but went so far as to advocate laparotomy when this could be done early, especially in the first six to eight hours, and certain Bulgarian reports seemed to confirm this. They stated that one advantage of early operation is that it may save some who would otherwise die of haemorrhage—a very important point. Lucas-Championnière, Reclus, Bozzi, and others advised conservatism unless operation could be performed early in a modern hospital. Kahn, writing in 1913, from experience in civil practice, says: "In every case of penetration of the abdomen by a bullet, multiple perforations of the viscera are to be assumed and prompt surgical exploration is demanded."

La Garde says: "It would seem to have been proved that the abdomen may be traversed by a missile without perforating hollow viscera, but perforation is the rule," and also that some cases recover spontaneously in spite of perforation. He quotes the case of Major Thornton, of the United States Army, who had 18 wounds of the intestine, but no complete perforation. He submits that the natural redundancy of the mucous coat, which fills the wound like a hernia, may prevent the escape of gas and faecal contents. He, however, comes to the conclusion that exploratory operation should be performed when environment permits.

In the early days in France nearly all these cases died, whether operated on or not. They were usually not received for many hours. Up to early in 1915, 85 per cent. of cases died by the time they reached England (Wallace). Schnieden states that spontaneous recovery is exceedingly rare, whilst recovery after operation was 27 per cent.

Up to the summer of 1915 the majority of the German surgeons at Lille advocated conservative treatment, but opinion was then changing. Demmer, writing in 1915, also advocated conservatism and gave a death-rate of only 24 per cent., but fuller particulars of these cases would be required before accepting them as perforating wounds. Friedrich gives interesting figures. 85 per cent. of cases treated without operation died within two days. Of those that reached the home hospitals (i.e., after two days), 38 per cent. died. Under conservative treatment the prognosis improved the higher up in the abdomen the wounds were inflicted, the best being in stomach and liver cases. Enderlen gives 30 per cent. recoveries after operation. Early in the present war he had operated as late as 18 to 24 hours after the wound occurred, but invariably found purulent peritonitis without adhesion of the abdominal organs or any sign of a mucous plug in the perforations. Prolapse cases ended fatally. Sauerbach endorsed the policy of operation in abdominal wounds and claimed 42.5 per cent. Korte states that the length of time that elapses before operation is the important factor; after

12 hours the prognosis is bad, especially if the case has been transported over rough roads.

Morley, after his experience in Gallipoli, writes: "It can generally be assumed where the wound of exit like that of entrance is the typical small puncture of the modern rifle bullet that the bullet will have drilled through the intervening viscera, causing holes no greater than in the skin, and that the redundant mucosa of the stomach or intestine will plug up the holes and prevent the escape of the contents, until plastic adhesions have completed the healing process." This to me is an astonishing statement, as all my experience went to show that the nature of the wounds gave little or no indication of the amount of the damage internally. Morley therefore adopted a routine treatment of morphia, Fowler position, and giving nothing by the mouth for 24 hours, with saline when necessary subcutaneously. Operation was undertaken if sufficiently obvious. In wounds inflicted by shell or shrapnel he advocates operation.

Mayo Robson, at the end of 1915, wrote that a clean bullet wound through the abdomen with small wounds of entry and exit and without evidence of internal haemorrhage or extravasation may, if favourably situated, be treated expectantly. But the trouble is that internal haemorrhage and extravasation may give no evidence until too late. He thought operation well worthy of consideration if early and the patient fit and in suitable surroundings.

Fraser and Bates, in their illuminating and conclusive paper, come to the conclusion that in the vast majority of cases of penetrating wounds of the abdomen operative measures offer the best chance of success, but qualify their statement by excluding from that category uncomplicated wounds of the liver and certain wounds of the kidney. My own experience is in almost entire agreement with theirs, and their interesting drawings depict conditions of the gut that were met with in very many of my cases.

Webb and Milligan would operate on most cases, but not at once on principle. They do not operate where there is doubt as to penetration, when the liver or the kidney alone is involved or when the case is moribund. They give a full account of their methods of examination and of the clinical signs one meets with in these cases. With them Crisp English is in agreement, but excepts also a diaphragmatic group with extensive injury to the lower chest and upper abdomen. He often postponed operation in shock and haemorrhage cases. He states that spontaneous recovery is a very rare event and that wounds of the central and lower abdomen are fatal if left alone.

My own experience of some 90 cases, together with particulars supplied by my colleagues of a dozen more, has led me to conclusions which agree in the main with those expressed in the last three papers. In 10 months of the early part of the war, between November, 1914, and October, 1915, only 10 cases of penetrating abdominal wounds among the Indian troops arrived at the base hospital at Busra, to which all cases came—that is to say, the other cases died within a day or two. Of these 10, nine died, whilst the tenth was transferred to India, and I am ignorant of his fate. It was a case with an entrance wound only, and it is quite likely that he would require an operation later for faecal fistula. None of these cases was received within 20 hours of injury, and some of them had been wounded for a much longer time; none was operated on. Similarly, of the 44 Kut cases that were not operated on, 41 died, and of the three that survived two were "liver only" cases. The third (Case 22) was a lower abdomen case, and the only one I have seen recover without operation. These figures are sufficient to emphasise the appalling mortality of abdominal wounds in the lower part of the belly and the urgent need for active treatment. By "lower part" I mean any portion below the transpyloric plane, which serves as a rough guide. "Operation on principle" refers to this part. It had always seemed to me that these cases should be treated as acute abdominals, and that operation held out the only reasonable hope of recovery, provided that they could reach a stationary hospital before serious peritonitis set in. The investment of Kut provided an unusually good opportunity of getting these cases within a very short time after they were wounded. Colonel Patrick Hehir, C.B., was good enough to arrange that all abdominal cases should be sent at once to the General Hospital whenever this was possible, with the result that many of them were admitted within from 15 to 60 minutes. Thirty were admitted within an hour of injury.

Many of these, of course, were cases such as ordinarily die on the field of battle and do not reach a hospital at all, but one or two were saved who would otherwise have died from haemorrhage or who would have been beyond hope of operation by reason of haemorrhage had they been admitted later. Herein lies the importance of immediate operation unless one can be reasonably sure that serious haemorrhage is not taking place. By serious haemorrhage is meant bleeding rapid enough either to be fatal within a few minutes or so to reduce the strength of the patient in an hour or two as to contra-indicate operation. If one can be reasonably sure, then it is obvious that anti-shock measures and time given to the patient to recover from the shock of his injury are of paramount importance, since leaving him for five or six hours does not, I think, add seriously to the risk of severe peritonitis. But I have found it sometimes extremely difficult to be sure just when to leave patients, for the changes in the pulse may not be at all alarming, and may fall very far short of what one is accustomed to appreciate as a bleeding pulse long after the bleeding has gone on to a dangerous extent, when the effect of the operation is added thereto. Unfortunately, a large number of these cases do bleed, and there seems to be little or no tendency for the haemorrhage from ruptured vessels in gut or mesentery to stop. Several times I have been astonished on opening an abdomen to find a large quantity of blood in the peritoneal cavity such as one would have thought would have had a very definite effect on the pulse, whereas a very few beats above the normal has been all the evidence obtainable. Moreover, I am inclined to think that the shock of opening the abdomen and consequent exposure of the intestines to the air, whether Yandell Henderson's CO<sub>2</sub> theory be correct or not, is considerably accentuated after even moderate bleeding, and this has to be taken into account before deciding to wait.

As regards the question of operating on these abdominal cases or indulging in expectant treatment, I would operate on all cases of penetrating wounds below the transpyloric plane as a routine method, provided, of course, that the patient be considered fit enough to stand the operation. The length of time that may be allowed to elapse before operation will vary with the condition of the patient and the existence or probability of haemorrhage. If there is bleeding operation must be undertaken at once; if not, it is permissible to wait up to 8 or 9 hours. It is doubtful if, as a rule, operation is worth while after 12 or 14 hours have elapsed. Of 9 cases operated on after 12 hours or more, only 1 recovered. Of the 98 cases I am able to quote 42 were operated on, with 10 recoveries. 90 of the cases were wounds below the transpyloric plane, and of these 40 were operated with 9 successes. Of the other 50 one lived, one was awaiting operation just before the end of the siege, and the fate of the third is doubtful. These successes represent the minimum number possible. Under better conditions more would have lived. I have no doubt also that operating on several of the bleeding cases was of the nature of a forlorn hope, and I now feel that some of the others might have been all the better for more prolonged anti-shock treatment, but this was difficult to give. Of wounds above the pyloric plane 2 were operated on with one recovery, and of the 6 unoperated on 3 lived. Of these 2 were "liver only" cases, and in the third the bullet just skimmed the under surface of the same organ (Case 88).

The cause of death in the majority of cases was a combination of haemorrhage and shock; many died from the former alone. Those that survived the first two days died from peritonitis. Three died from this cause after operation. No case developed gas gangrene or spreading cellulitis. The amount of damage done to the intestine is practically always serious and varies greatly from one or two holes or rents to a dozen or more.

Clinical signs and symptoms are not a reliable guide to the extent of the lesions (*vide* Cases 7, 60, 15, 18, 20, 24, 25, 30, 35, 41, 42). Usually there are several holes or rents of all sizes from a threepenny-bit to a longitudinal rent several inches in length. I have only once seen a very small hole that might presumably have been occluded by natural means, and then it was not the only one; the average hole was about  $\frac{1}{4}$  to 1 inch in diameter, with thick pouting everted lips of contused mucous membrane. Fraser and Bates's pictures show the condition exactly. Sometimes the gut is almost completely severed as if it had been roughly cut; sometimes there are several holes or rents close

together, and when this happens resection is the only remedy. The mesentery was nearly always holed or torn and smaller or larger vessels generally involved and bleeding; the severed walls of the gut always bleed steadily.

Extravasation of intestinal contents had always taken place in greater or less quantity, that from the large bowel having a strong odour. In one case a round worm, 8 inches long, was found free in the peritoneal cavity. In wounds above the pyloric line the liver, stomach, and spleen are the viscera affected. Wounds of the liver are not necessarily very serious; a clean drilled hole through the organ soon heals up, whilst a gaping rent of moderate size is easily stitched up; moreover, haemorrhage from it tends to stop (Case 87). Wounds of the stomach are serious, and extravasation of its contents into the lesser sac is likely to occur as a complication, otherwise it is reasonable to suppose that small holes made in a single viscus whose walls are closely applied to solid structures might possibly become occluded naturally. The appearance of the external wound, unless very large, gives no information regarding the extent of the damage inside. Many of my cases had small external wounds co-existent with extensive lesions in the intestines.

As symptoms and signs, more or less pain is almost invariable, but I have seen one or two with practically none. I think it is less marked, as a rule, when there is much blood in the peritoneal cavity, bathing the torn tissues. Pain seems likely to be more severe with injuries low down in the pelvis. Vomiting is as often absent as present; rigidity and tenderness are almost always present; type of respiration varies with amount of rigidity. There is always more or less shock, but it, again, is not a reliable guide to the damage. The facies is, of course, a valuable indicator of shock and haemorrhage, but the pulse is the most important of all—its rate, and especially any increase in rate after a short interval, are the most important indicators of haemorrhage. Dullness in the flanks is seldom appreciable before the dangerous stage of haemorrhage is reached, and so is of little value. Distension is not present in the very early stages, but comes on later. Haemorrhage from the wound on meddling with it will sometimes give indication of the kind and extent of the bleeding. It is sometimes very difficult to decide whether penetration has occurred or not; the doubt should be cleared up by exploring the wound with the finger, first iodining the wound and enlarging it if necessary.

Little need be said on the subject of the operation. I used the most convenient incision in each case. Blood and contents obscuring the view are mopped up as quickly as possible. If the track of the bullet is accurately known examination of the whole length of the intestine is not always necessary and is inadvisable on account of shock. When the extent of the damage is known holes and rents are stitched up, by purse-string when very small, by through-and-through and Lembert when large; often, when hurried, I have used only one row of Lembert with no untoward result. After resection, end-to-end suture, but I have no doubt lateral anastomosis is better for the avoidance of post-operative gut paralysis. Resection appears to add considerably to the shock of operation. The peritoneal cavity is then cleaned and drained by a large  $\frac{1}{2}$  inch rubber tube from the recto-vesical pouch to the lower end of the incision; possibly also by an extra tube locally. The Trendelenburg position was often found useful. Chloroform was the only anaesthetic.

As post-operative measures the head of the bed was raised; salines were given if necessary; water by the mouth after 12 hours, milk-and-water after 24. Good nursing was badly needed. Distension usually occurred, but generally disappeared by the third day; when it did not, turpentine stupes and small doses of mag. sulph. usually defeated it. Slight bronchitis often caused trouble.

The following are brief notes of the cases.

CASE 1.—Sepoy, Infantry; bullet. Admitted Dec. 14th, 1915, 8 hours after injury. Entrance wound in right flank just above iliac crest; no exit; hit just after taking food. Condition: Pain considerable. Abdomen rigid and tender. Pulse fair in quality and slow; shock moderate. No history of vomiting. Operation. Laparotomy 10 hours after injury. Incision parallel to fibres of external oblique. Large quantity of intestinal contents free in peritoneal cavity. There were two large holes in the small intestine near each other on opposite sides with everted edges. No chance of natural occlusion. These were closed by purse-string sutures. Bullet

not found. Result: Recovery. Had some griping pains after getting on to light diet.

CASE 2.—Driver, Mule Corps; bullet. Admitted Dec. 18th, 1915. Wounded same day. Entrance wound small; 2 inches above middle of left Poupart's ligament; no exit. Bullet palpable in left buttock near middle line, low down. Condition fair; pain moderate. Abdomen rigid and tender. No history of vomiting. Operation about 12 hours after injury. Incision 1 inch to left of middle line. The peritoneal cavity was full of bloody urine, with commencing peritonitis. There was one wound in the bladder, which was stitched up. No other intra-peritoneal wound. The peritoneal cavity was swabbed clean and drained at the lower angle of the wound from the recto-vesical pouch. Shock very considerable. Result: Died. Abdomen remained distended. Urine passed naturally but stools contained blood. No temperature. Death from exhaustion and peritonitis on sixth day.

CASE 3.—Sepoy, Punjabis; bullet, on Dec. 20th, 1915. Admitted 18 hours after injury. Entrance wound over left hip; no exit. Condition: Considerable pain in abdomen, also behind right trochanter. Abdomen stiff and tender. No history of vomiting. Not operated on. Urine drawn off clear early on 21st. Result: Died on 22nd.

CASE 4.—Cook, Indian General Hospital; shell wound. Wounded Dec. 13th in hospital and seen at once. One wound lower part of abdomen. Condition: Shock moderate. No vomiting. Much pain and tenderness. Rigidity slight. No signs of bleeding. No dullness in flanks. Pulse-rate not appreciably increasing. Operation 3½ hours later. Pararectal incision. Good deal of blood in peritoneal cavity and bleeding still going on from mesenteric vessels. Several holes in small intestine which were stitched up by Lambert sutures. Segment of shell found resting in recto-vesical pouch. Peritoneal cavity cleaned and drained. Result: Died next day from shock and haemorrhage.

In this case operation was delayed a little to enable the patient to recover from the shock, but unfortunately, as so often happens, small mesenteric vessels continued to bleed and jeopardised his chances. An earlier operation would have stopped this, with perhaps a different result.

CASE 5.—Sepoy, Pioneers; bullet. Admitted Dec. 20th, 12 hours after injury. Entrance wound just to left of umbilicus; exit behind left flank. Rough journey to hospital. Condition: No notes. Operation about 14 hours after injury. Gut very badly damaged with bleeding from mesenteric vessels. Large amount of blood in cavity. Resection of 12 inches of small intestine. Peritoneal cavity was full of intestinal contents. Result: Died same evening, haemorrhage and shock.

CASE 6.—Syce; bullet. Admitted Dec. 13th, 1915, 20 hours after injury. Lower half abdomen. No operation. Died Dec. 16th from peritonitis.

CASE 7.—Sepoy, Mahrattas; bullet, .377 uncased. Admitted Dec. 24th, 1915, five hours after injury. Entrance wound left buttock near middle line. Bullet could be felt subcutaneously 2 inches to left of umbilicus. Condition good, not much pain; some tenderness and rigidity. No note of vomiting. Facial expression normal. No signs of bleeding. Pulse and respiration unaffected. Operation one hour later, median incision. Peritoneal cavity was full of intestinal contents and very dirty. There were five holes in the small intestine, which were sewn up and the peritoneal cavity cleaned and drained. Result: Uninterrupted recovery; some hiccough on third day.

CASE 8.—Water-carrier; bullet. Admitted Dec. 28th, 1915, within two hours of injury. Entrance wound left flank. Exit same level 2 inches to right of umbilicus. Condition: Very pale and collapsed; no pulse. Operation not indicated. Result: Died within few hours.

CASE 9.—Sepoy; bullet. Too bad for operation; did not recover from shock and died next morning, Dec. 11th, 1915. Lower abdomen.

CASE 10.—Cook, Rajputs; bullet, lower abdomen. Admitted Dec. 11th, within two hours and died same day; too bad for operation.

CASE 11.—Arab coolie; bullet. Admitted Jan. 8th, 1916, within an hour of injury. Entrance wound somewhat large and ragged in left flank two inches above iliac crest; small piece of omentum protruding; no exit. Condition good, pain considerable. Tenderness and rigidity on right side of abdomen. No vomiting. No signs of bleeding. Operation two hours later. Incision transverse, muscle splitting, wound excised. There was some extravasation of the contents of the large bowel. Three holes in the descending colon stitched up and the peritoneal cavity cleaned and drained. Owing to condition of patient the operation was hurried. Bullet not found. Result: Next day abdomen was soft, but slightly distended and tender, but pulse fairly good. Vomited twice. Next day he was given solid food by his relatives, but nevertheless made an uninterrupted recovery and was running about in three

weeks. He returned to full coolie work towards the end of March.

CASE 12.—Sepoy, Infantry; bullet. Admitted Dec. 19th, 1915, 24 to 36 hours after injury, lower abdomen. No operation; died next day.

CASE 13.—Sepoy; bullet; pelvis. Admitted Dec. 15th, 1915, about 48 hours after injury. No operation; died next day.

CASE 14.—Driver; bullet, lower abdomen. Admitted Dec. 13th, 1915, about 20 hours after injury. No operation; died next day.

CASE 15.—Dhooly-bearer, Field Ambulance; large Arab bullet. Admitted Jan. 1st, 1916, 2½ hours after injury. One wound only in left flank, mid-axillary line, just above crest of left ilium; no indication of direction save that he was standing up when hit. Considerable pain, right half of abdomen rigid and tender; no vomiting; bleeding probable. Operation one hour later. Incision in direction of external oblique, internal oblique split. There were several large holes in the small intestine, plus a rent in the mesentery, from the vessels of which considerable bleeding was taking place. The vessels were tied, two holes closed by Lambert sutures, and a piece of badly injured gut where there were three holes close together was resected, the ends of the intestine being joined by end-to-end anastomosis. Patient had lost a good deal of blood, and there was much shock. The bullet was not found. Rectal salines were administered. Result: Next day abdomen not distended, but somewhat rigid and tender; large amount of sanguineous fluid drained away; did not recover from shock and died at 2 o'clock.

CASE 16.—Lance-Corporal, Infantry; shrapnel wound abdomen and both arms. Admitted Jan. 15th, 1916, wounded about 4 P.M., seen two or three hours later. Entrance wound just to left of umbilicus, exit left buttock. Condition fair, bleeding doubtful. Operation, 8 P.M. Bleeding from torn vessels in pelvic mesocolon; four large holes in small intestine sewn up, and one in mesocolon; abdominal cavity cleaned and dried. Track of bullet went through iliopsoas just external to external iliac artery and through ilium. Wide patent track through buttock to external wound. Patient took anaesthetic badly, stopping breathing several times, and vomiting strenuously at end of operation. Result: On 16th abdomen still stiff, not distended; fair amount of sanguineous discharge. Good deal of pain. Pulse rapid and poor. No vomiting. On 17th abdomen softer and patient looking well, but died suddenly of heart failure at 2 P.M.

CASE 17.—Sepoy, Punjabis; bullet. Admitted Jan. 21st, 1916, one hour after injury, in very bad condition from shock and haemorrhage; vomited coffee-ground material half an hour later. Entrance wound left side of back over tenth rib; exit left side of epigastrium. No operation; died during night.

CASE 18.—Sepoy, Punjabis; bullet. Admitted Jan. 21st, 1916, about one hour after injury. Entrance wound 3 inches to right of spine at level of costal margin; exit just above costal margin over tenth rib, the cartilage of which was broken; omentum protruding. Condition not good; bleeding doubtful. Operation an hour later. Two wounds in hepatic flexure and two in liver stitched up. Good deal of blood exuded from liver. Result: Died 24 hours later.

CASE 19.—Sowar, Cavalry; bullet at long range. Admitted Jan. 21st, 1916, within an hour of injury. Entrance wound small, in left hypochondrium; no exit. Condition bad; blanched, very cold, and restless; pulse imperceptible at wrist. Abdomen moved freely but was somewhat distended; no dullness in flanks; no vomiting. No operation; died in half an hour from shock and haemorrhage.

CASE 20.—Lance-Naick, Mule Corps; bullet, at long range. Admitted Jan. 21st, 1916, about an hour after injury. Entrance wound left flank; no exit. Condition bad; bleeding probable. Operation within an hour. There was one rent in the small intestine 2½ inches long in the long axis of the gut and two other smaller ones. The mesentery was torn and its vessels bleeding. All were stitched up. Result: Died during the night; shock and haemorrhage.

CASE 21.—Private, Infantry; bullet. Admitted Jan. 21st, 1916, about seven hours after injury. Entrance wound right buttock, near middle line; exit midway between umbilicus and pubes, ½ inch in diameter, slightly to right of middle line. Condition: Very little pain. Abdomen rigid; pulse fair; no vomiting; urine clear. Treated expectantly. Next day some vomiting, otherwise condition unchanged. On the third day the abdomen was softer and almost painless, but slightly tender in the left iliac region, and he looked in fair condition, but he was vomiting bilious matter and his pulse was almost imperceptible at the wrist. He died later in the day. There is no doubt that this case should have been operated upon, and I regret I did not do it.

CASE 22.—Sepoy, Punjabis; bullet. Admitted early in December, 1915. Entrance wound left side back over tip of twelfth rib cartilage. Bullet extracted from abdominal wall 1 inch internal to and above right anterior superior iliac spine. There was much pain in the abdomen and in the sole of the right foot. There was no vomiting and never any blood in the stools or urine, but he passed urine with difficulty. There was paralysis of the left leg. This man recovered; he had no further abdominal symptoms, but his paralysis persisted with only very slight improvement.

*Note.*—This is the only case of a penetrating wound below the pyloric line that I have seen recover without operation, and even in this case it is possible that the bullet passed along beneath the fascia covering the psoas and illacus. I count it, however, as a perforating wound.

CASE 23.—Arab girl, aged 8 years; bullet. Admitted Jan. 27th, 1916, about one hour after injury. Entrance wound right side epigastrium, small; exit just below costal arch 1 inch outside left nipple-line, 1 inch in diameter; omentum and about 12 inches of colon extruded. Condition fair, but restless and frightened; probably bleeding. Operation one hour later; one hole in splenic flexure, one large and one small hole in stomach. Under surface of liver torn. Bleeding vessel in stomach wall. Good deal of blood in peritoneal cavity. Result: Died same night, haemorrhage and shock.

CASE 24.—Rifleman, Gurkhas; bullet, probably large. Admitted Feb. 2nd, 1916, about three hours after injury. Entrance wound right hip at tip of great trochanter; exit 2½ inches to left of umbilicus, large and lacerated, 2 inches in length. Condition fair, but evidence of bleeding; pain severe, some tenderness in abdomen. Operation: Median incision; much fresh blood in peritoneal cavity, from branch of superior mesenteric in torn mesentery. Six holes in small intestine, three large and three small. Result: Recovery; vomited twice during night; next day abdomen slightly distended. Third day, abdomen normal and not tender; troublesome cough, otherwise uninterrupted convalescence,

CASE 25.—Driver; bullet. Admitted Feb. 2nd, 1916, 2½ hours after injury. Entrance wound 2½ inches to left of umbilicus; no exit. Condition: Blanched, not much pain, but complained of pain and tenderness on right side of abdomen. Pulse small and increasing slowly in rate. Operation three hours later. There was a large quantity of blood in the peritoneal cavity; a large rent in the mesentery near the ileo-cecal junction; the bleeding was coming from the ruptured ileo-cecal artery. There were eight holes in the small intestine and one in the cæcum; all sewn up. Patient very collapsed. Rectal salines, &c. Result: Died shortly afterwards; death due principally to haemorrhage.

*Note.*—It was very unfortunate that this case and the previous one came in at the same time and that both were bleeding, so that one of them had to wait. By the time the first operation was finished this man had lost a lot more blood, and died in consequence.

CASE 26.—Arab; bullet. Admitted Feb. 18th, 1916, half an hour after injury. Entrance wound 1½ inches above navel, ½ inch in diameter; exit wound outer edge of right erector spinae, 2 inches above iliac crest. Condition apparently good, abdomen soft. Pulse normal rate and of good quality, but within half an hour, when ready for operation, the pulse had become very feeble and over 100 in rate and vomiting and restlessness had set in, evidently due to severe internal haemorrhage. No operation. Patient died in the next half hour.

CASE 27.—Rifleman, Gurkhas; bullet. Admitted Feb. 20th, 1916, one hour after injury. Entrance wound small, over tip of left trochanter; exit 2 inches above and behind right trochanter, large, and tissues lacerated to considerable extent. Condition bad, much shock; severe pain in abdomen, generalised; no rigidity, but tenderness on pressure over hypogastrium. No operation. Death four hours later. No note of vomiting.

CASE 28.—Sepoy, Rifles; bullet. Admitted Jan. 29th, 1916, about 14 hours after injury. Entrance wound right buttock ½ inch from middle line at level of second piece of coccyx. No exit, but bullet could be felt beneath skin of abdomen 2 inches above pubes and to left of middle line. Condition fair; abdomen somewhat rigid and painful above pubes. Some dullness above pubes, ? bladder. Pain severe; lies on left side. Some bleeding from entrance wound. A catheter introduced before admission brought off bloody urine. No vomiting. Operation two hours later; median incision. Much bloody urine in peritoneal cavity, slightly faecal-smelling. There was one hole at the apex of the bladder admitting tip of index finger and another in the base; from this the track led into the rectum. At this stage of the operation the patient stopped breathing, and despite all the measures we could take died on the table. This was most unfortunate as the prognosis seemed favourable.

CASE 29.—Sepoy, Rajputs; bullet. Admitted Feb. 11th, 1916, about 2 hours after injury; wounded in arm and abdomen. Had lost a lot of blood from the wounds in the arm. Entrance wound in abdomen in left flank just below costal margin in mid-axillary line. Exit, right side, 1½ inches external to margin of right erector spinae midway between ribs and ilium. Condition poor, pulse weak; much pain on left side, no vomiting. Urine passed at 6.30 (wounded at 4) contained no blood. Abdomen stiff, especially on left side. No paralysis; said he was bending at time of hurt. Operation, 7.45 P.M.: Incision parallel to and 1½ inches below left costal margin; internal rectus split. There were some faecal contents in peritoneal cavity; one hole, ½ inch wide, in outer wall of descending colon. Result: Next day abdomen softer but pulse still bad. Died following day. Did not get nourishment ordered during night. His death was disappointing, but was largely due to the initial haemorrhage.

CASE 30.—Sepoy, Sappers and Miners; bullet. Admitted Feb. 12th, 1916, 5½ hours after injury. Entrance wound 2 inches below right iliac crest just behind tensor fasciae femoris, small. Exit just to left of and below umbilicus, 1 inch in diameter and bloody fluid exuding from it. Condition, much shock, pulse feeble. Great pain in abdomen, moderate rigidity. Advisability of operation very doubtful. Operation 1½ hours later. Peritoneal cavity full of intestinal contents, including recent food, grains of barley, &c. There were many large holes, eight or nine, some of which were complete rents of the small intestine, and none so small as to suggest that they could be closed by natural means. There was a good deal of blood in the pelvis, but no ruptured mesenteric vessel. All were sewn up. Pulse at the end of operation seemed no worse. Result: Did not rally and died next day.

CASE 31.—Havildar, Rifles; bomb from aeroplane. Admitted Feb. 13th, 1916, half an hour after injury. One wound, small, 2½ inches to right and below umbilicus; signs of haemorrhage; pulse feeble and quick. Operated at once in the hope of stopping the bleeding. There was a large amount of blood and clots in the peritoneal cavity, and much faeces and a large rent in the cæcum. The man died half an hour after operation from haemorrhage and shock.

CASE 32.—Sepoy, Pioneers; bullet. Admitted Feb. 14th, 1916. Wounded right flank. Operation within four hours. There was one small hole in the ascending colon near hepatic flexure with much bruising. Patient died on the third day. The notes on this case are, unfortunately, meagre.

CASE 33.—Sowar, Cavalry; bullet at long range. Admitted Jan. 21st, 1916, an hour after injury. Entrance wound over left hypochondrium, small; no exit. Condition bad; complained greatly of cold and was very restless. Abdomen moved freely on respiration, but was somewhat distended. No dullness in either flank. Pulse imperceptible at wrist. Died half an hour later.

CASE 34.—Water-carrier; bullet. Admitted Feb. 20th, 1916, 18 hours after injury. Entrance wound 4 inches behind and below right anterior superior iliac spine; exit, right chest, 2 inches below and external to nipple; probably pierced ascending colon and liver. Condition bad, facies anxious; had been vomiting. Abdomen painful over right half and over left hypochondrium, tender and very rigid. Pulse 95. No operation. Died next day from shock and peritonitis.

CASE 35.—Lance-Naick, Mule Corps; bullet. Admitted Feb. 20th, 1916, half an hour after injury. Entrance wound near middle line over fourth piece of sacrum. No exit, but evidence of bullet in abdominal wall 3 inches to right of umbilicus. Condition: Had been vomiting. Severe pain and lies on right side. Abdomen tender, but only moderately stiff. Pulse normal in rate and of very fair quality. Operation an hour later. Good deal of dark blood and clots in peritoneal cavity. There were nine holes in the small intestine and one in the upper part of the rectum. In two places the damage to the small intestine was so extensive that resection of 6 and 8 inches respectively was necessary; the others were stitched up by Lambert sutures. Patient took anaesthetic badly and died at end of the operation.

CASE 36.—Driver, Mule Corps; bullet. Admitted Feb. 22nd, 1916, within half an hour of injury. Entrance wound 4 inches behind right anterior superior iliac spine, small and round; exit 2 inches to right and a little below umbilicus, also small. Condition fairly good. Had vomited two or three times. Pain not severe, abdomen not rigid, but tender in right lower quadrant. Pulse slow and of fair volume. Operation half an hour later; incision medial to outer edge of rectus. There were a few ounces of blood in the peritoneal cavity and a little intestinal contents. Five holes in the small intestine, one of which was 1½ inches long, the others round and two of them small enough for purse-string suture. No special vessel was bleeding. Most of the blood appeared to have come from the wounds in the parietal peritoneum. Result: Recovery. Next day there was some distension and tenderness and the pulse was

feeble, but on the third day he passed a motion and the distension disappeared. The pulse improved and convalescence was uninterrupted.

CASE 37.—Arab coolie; bullet. Admitted Feb. 25th, 1916, two hours after injury. Entrance wound 4 inches below right nipple, no exit but a large round soft swelling 4 inches in diameter over ninth rib in mid-axillary line, left side; liver, stomach, and probably spleen involved. Condition poor; man aged 58, facies anxious, some bleeding from entrance wound, vomiting small quantities of mucus, &c. Very cold. Much pain in epigastrium. Upper abdomen rigid, but not very tender; lower abdomen soft. Pulse 85, small, soft, compressible. No operation. Died 3½ hours later.

CASE 38.—Lance-Naick, Mule Corps; bullet. Admitted Feb. 27th, 1916, three-quarters of an hour after injury. Entrance wound 3 inches to right of umbilicus; exit 3 inches below and behind left anterior superior iliac spine. Condition, 15 minutes after arrival, bad; considerable pain and good deal of tenderness, especially near entrance wound, but only slight rigidity. Pulse 90 and much worse than 10 minutes ago, evidently bleeding; 10 minutes later, 110 and weaker. Patient getting restless and cold, and vomited twice. No operation. Died an hour later.

CASE 39.—Private, Infantry; bullet. Arrived at dressing station only and died in 15 minutes. Wounded in lower abdomen from flank to flank. Death from haemorrhage.

CASE 40.—Gunner, R.F.A.; bullet. Admitted March 1st, 1916, about 1½ hours after injury. Entrance wound 3 inches to right of twelfth dorsal spine; exit just over surface-marking of pylorus. Condition not good; considerable shock; had vomited. Great pain; abdomen absolutely rigid and very tender. Pulse slow and somewhat irregular; volume moderate; probably some bleeding; 1 gr. morphia given. Operation 1½ hours later. There was a large longitudinal rent in pyloric end of stomach, 1½ inches long, and a similar one over pylorus itself. Much exudation of stomach contents and considerable amount of blood, most of which came from the liver, which had a small rent in it between the two lobes. Result: Vomited several times during the night. Next day abdomen still stiff and tender. Much bile on dressings. Pulse faster and weaker. Did not rally from shock and died same day.

CASE 41.—Sepoy; bullet. Admitted 3.30 P.M. on March 1st, 1916, 2½ hours after injury. Entrance wound right flank about middle of iliac crest; exit through left chest 1 inch external to nipple line at level of sixth rib. Omentum protruding through exit wound. Condition: Great pain and tenderness, but not much rigidity; had vomited. Pulse 95 and of poor volume, suggesting haemorrhage. Operation within half an hour. Abdomen was absolutely full of faeces and blood, some of it from the liver. Very extensive damage to the transverse colon. Patient's condition did not admit of any complete operation, so the cavity was quickly cleaned and a hasty colotomy done, but he died in an hour, mostly from haemorrhage.

CASE 42.—Private, Infantry; bullet. Admitted March 3rd, 1916, half an hour after injury. Entrance wound 2 inches above left trochanter. No exit. Man was in the act of defaecating when hit. Condition: Lay on right side, severe pain; very rigid, much vomiting; pulse slow and good. Operation half an hour later. There were 11 holes in the intestine, 3 in the large and 6 in the small, and 1 on each side in the pelvic walls, low down, below the internal iliacs, from which was considerable bleeding; no bleeding point found. Blood in cavity ½ to ¾ pint. Result: Remained in great pain and did not rally; died next day.

CASE 43.—Lance-Naick, R.F.A.; bullet. Admitted March 6th, 1916, half an hour after injury. Entrance wound 2 inches internal to right anterior superior iliac spine; exit left buttock 4½ inches below and behind left anterior superior iliac spine. Right forearm also wounded. Condition: Great pain, abdomen rigid, considerable bleeding. Pulse about 80 and of moderate volume. Not specially distressed. Operation half an hour later; rectus incision. Abdomen full of blood, mostly venous, the bleeding coming from wounds in gut and from four rents in mesentery, especially two of the latter. Five holes in small gut of varying sizes from ½ to 1½ inches, 4 in mesentery. Result: Died 4 hours later, chiefly due to haemorrhage.

CASE 44.—Sepoy, Punjabis; bullet. Admitted fifth day after injury. No operation. Died sixth day; peritonitis.

CASE 45.—Lance-Naick, Gurkhas; large bullet. Admitted March 11th, 1916, about an hour after injury. Entrance wound left flank; large, round. Complained of great pain; abdomen slightly tense; pulse very good and slow. No note of vomiting. Operation an hour later. There was a lot of arterial blood in the peritoneal cavity, mostly coming from an artery in the pelvic mesocolon; four holes in small intestine, four in mesentery, and two in rectum. Result: Did well at first; there was no distension. He passed faeces and

urine naturally, and condition generally on the third day seemed very favourable, but on the fourth day there was distension, which was relieved a day later by small doses of mag. sulph. and turpentine stupes. On the 15th he started diarrhoea, which persisted for some days, and the discharge became somewhat offensive; the lower abdomen ceased to move with respiration and became tender and painful. He steadily went downhill unfortunately, and died rather suddenly on March 22nd. Possibly some of my stitches broke down, but I did not feel justified in opening him up again.

CASE 46.—Arab girl, aged 14; bullet. Admitted March 14th, 1916, 1½ hours after injury. Entrance under right flank, just above costal margin, 1 inch behind the mid-axillary line; exit 2 inches below xiphisternum. Small tag of omentum protruding from anterior wound. General condition not good; pain and shock, slight rigidity. Pulse slow and fairly good. Operation half hour later. One hole in hepatic flexure; a large hole and rent 4 inches long in right lobe of liver, 1½ inches from lower margin. Anterior portion of right lobe button-holed; gall-bladder bruised. Result: Did well at first, but developed pyo-pneumothorax and died on April 7th from septic exhaustion. There was no trouble with the intestinal condition; the abdomen remained soft and painless and the bowels normal.

CASE 47.—Private, servant; bullet, .400 uncased. Admitted March 15th, 1916, within half an hour of injury. Entrance wound 2 inches below and 1 inch behind left anterior superior iliac spine; no exit. Condition: Great pain, especially around navel, and tenderness. Burning sensation extending from left iliac region to navel. Abdomen slightly tense; vomited once. Pulse slow and of fair quality. Operation half an hour later. Took anaesthetic badly. There were 2 holes in the pelvic colon; 2 semi-holes in the cæcum, near which lay the bullet; 3 holes in the small intestine, one 1½ inches the others ½ inch in diameter; 2 large holes in the mesentery, one of which was bleeding. Result: Did not rally from shock and died 20 hours later.

CASE 48.—Sepoy, Infantry; bullet. Admitted March 17th, 1916, 10 hours after injury. Entrance wound 4 inches behind right anterior superior iliac spine; exit 2½ inches medial to it. Condition: Old man with pyorrhœa alveolaris. Great pain; abdomen very rigid; pulse about 90, poor. Had drunk 2 ounces of milk, given him by an orderly. Operation 3 hours later; bleeding moderate. Good deal of extravasation of intestinal contents, mostly grass. Seven holes in small intestine, in size from a pea to half-a-crown; a small portion had to be resected. Pulse at end very bad. All possible shock measures taken. Result: Improved during first few hours, but died on following day.

CASE 49.—Sepoy, Infantry; bullet. Admitted March 19th, 1916, about 15 hours after injury. Sent in as gunshot wound of the thigh. Entrance wound to right of fourth vertebral spine; exit 1½ inches above middle of right Poupart's ligament. Condition: Pale, anxious, and tired-looking. Abdomen distended and tense; considerable pain and tenderness. Pulse slow and good. Operation an hour later; paracentral incision. Considerable amount of blood diffused in peritoneal cavity. Small intestine blown up. Two holes in cæcum: one ½ inch, one ¼ inch; local peritonitis. Result: Recovery. Distension persisted for a couple of days, but began to disappear after a simple enema in the evening of the second day.

CASES 50, 51, 52.—Private, sergeant, and private. All wounded by bomb which fell in hospital. In No. 51, who was operated on first, there was prolapse of several feet of small intestine and the cæcum, a 3-inch hole in the parietes, and another of 1½ inches. There were three holes in the small intestine, and the cæcum was badly torn and bruised. The small holes were stitched up and a colostomy done. In No. 50 there were four holes in the small intestine and a piece of bomb was removed from the gut. No. 52 bled a lot before he could be attended to, and had sustained damage to the cæcum and the small intestine. All died within the next two days.

CASE 53.—Arab; bullet. Admitted March 23rd, 1916, within an hour of injury. Entrance wound 1½ inches above left trochanter; no exit. Condition: Poor, aged 55, pyorrhœa alveolaris; pulse slow but poor volume and tension; bleeding probable. Good deal of shock. Operation 1½ hours after injury. Large quantity of arterial blood in peritoneal cavity, also a large round worm and other intestinal contents. One large rent and one smaller hole in small intestine. Entrance and exit wounds in recto-vesical pouch, from which some bleeding. Result: Died next day, mostly due to haemorrhage.

CASE 54.—Sepoy; bullet. Admitted March 23rd, 1916, at 10 P.M., soon after injury. Entrance wound 2½ inches above posterior superior iliac spine. No exit, but bullet lying under skin near McBurney's spot. Condition good. No vomiting. Operation, 11 P.M.; diagonal incision. One small hole in cæcum stitched up; bullet removed. Result: Uninterrupted recovery.

CASE 55.—Sepoy, Infantry; bullet. Admitted 2½ hours after injury. Entrance wound 2 inches above and behind left anterior superior iliac spine. Exit 4 inches behind and 2 inches below right anterior superior iliac spine. Condition poor. Pulse 70, poor. Abdomen painful, rigid, and tender; considerable shock. Decided not to operate unless improvement set in. An hour later pulse 90 and worse. No operation. Died in 6 hours.

CASE 56.—Sowar; bullet. Admitted three or four days after injury. Abdomen swollen and distended. Laparotomy undertaken for drainage. There was a hole in the transverse colon and the omentum was gangrenous. Pus in abdominal wall and in peritoneal cavity. Death three days later.

CASE 57.—Private, Infantry; bullet, .400 uncased. Admitted half an hour after injury. Entrance wound 1 inch to right and below umbilicus; no exit. Condition: Very restless and shocked, pale, anaemic. Pulse small, soft, slow. Abdomen very painful and somewhat rigid; had vomiting severely. No operation. Died next morning; haemorrhage and shock.

CASE 58.—Naick; bullet. Admitted March 28th, 1916, 2½ hours after injury. Entrance wound 2 inches above and medial to left anterior superior iliac spine; exit 5 inches below and behind right anterior superior iliac spine. Great pain, some rigidity and tenderness, no vomiting. Not blanched. Pulse 70; not too good. Operation an hour later. Loss of blood not excessive. Ten holes in small intestine; one in large, descending colon. The ten former were stitched up, the latter left as colotomy owing to condition of patient. Result: Pulse very variable during operation; very restless afterwards. Died third day from shock.

CASE 59.—Lance-Naick; bullet. Admitted March 29th, 1916. Entrance wound near twelfth dorsal spine; no exit. Great pain in epigastrium and tenderness. Slight rigidity in upper abdomen; no vomiting. Pulse very poor, 80, small, low tension. Died same night, probably haemorrhage.

CASE 60.—Arab girl, aged about 8; bullet. Seen in her home about 2 hours after injury, when there were no abdominal symptoms and viscera were thought to have escaped. Entrance wound 1½ inches above pubes 1 inch to left of middle line; exit right hip 2 inches behind anterior superior iliac spine; ? injury to bladder. Next morning, 17 hours after injury, symptoms of peritonitis; temperature 103° F. Operation: Two small holes in bladder, one in small intestine around which peritonitis. Patient died suddenly four hours later. This case should have been saved; thorough exploration of the wound would probably have revealed the condition and have been followed by operation.

CASE 61.—Private, Infantry; bullet. Admitted March 30th, 1916, 45 minutes after injury. Entrance wound 2 inches behind left anterior superior iliac spine; no exit. Had had morphia. Sitting down when hit. Condition: Semi-blanching and sweating. Comfortable, little or no pain. Abdomen fairly soft, no tenderness. Pulse imperceptible at wrist. Died same afternoon.

CASE 62.—Sepoy, Rajputs; bullet, April 1st, 1916. Seen within few minutes. Lower abdomen; prolapse of omentum; vomited, no rigidity, bleeding pulse. Died in half an hour.

CASE 63.—Similar case, lower abdomen. Died in 15 minutes, probably haemorrhage.

CASE 64.—Sepoy, Punjabis; bullet. Admitted April 11th, 1916, half an hour later. Entrance wound 1 inch to outer side of left posterior superior iliac spine; no exit. Was standing up when hit. Condition, shocked; great pain in stomach; had been given opium. Hands cold. Abdomen tense and tender all over. Pulse 75, regular, fair volume, low tension. Considered not bleeding seriously, and decided to await recovery from shock. Seven hours later pulse better; tenderness referred especially to right side abdomen. Operation an hour later—i.e., 8½ hours after injury. Haematoma in right abdominal wall. Considerable amount of blood in peritoneal cavity. Good deal of peritonitis on several coils of intestine; .400 uncased bullet found lying in peritoneal cavity. Six holes in small intestine, four of them large; one in mesentery. Stood operation well, but pulse irregular at times. Result: Recovery. Some slight distension first two days, and ran temperature from fourth to seventh day; some cough for few days.

CASE 65.—Sepoy, Sappers; .303 bullet, self-inflicted. Admitted half an hour afterwards, on April 13th, 1916. Entrance wound ½ inch to left and above umbilicus, omentum protruding and venous blood exuding on movement; exit 2½ inches left of middle line at back, same level. Both wounds small and round. Patient very pale, cold, restless, and pulseless. Abdomen soft, not tender. Died in half an hour; haemorrhage.

CASE 66.—Sweeper, Infantry; bullet. Admitted April 16th, 1916, half an hour after injury. Entrance wound 2 inches above left costal margin, just outside nipple line; exit 2 inches below right costal margin 1½ inches outside nipple.

Left rib broken; arm wounded. Condition fair, no vomiting. Abdomen semi-rigid and very tender. Pulse 80, ? increasing in rate, fair quality, some sweating. Operation half an hour later; moderate amount of blood; some bile and good deal of stomach contents. Three holes in stomach, ½ to 1 inch long, two in gall-bladder. Gastro-hepatic omentum torn, whence some bleeding. Small rent in liver, of which bleeding stopped. Both sacs drained. Result: Died third day.

CASE 67.—Lance-Naick, Punjabis; bullet. Hit midnight April 18th, 1916. Wounds side to side near iliac crests. Brought into regimental hospital in early morning with distended abdomen, greatly diminished liver dullness. Thin pulse, 45; body cold. At the general hospital at 10 o'clock. No pulse at wrist, carotid 120; dull in both flanks. Breathing laboured. Abdomen rigid and tender. Died at 2 P.M.

CASE 68.—Arab; bullet. Admitted April 18th, 1916, 21 hours after injury. Entrance wound left of spine; exit left flank. Abdomen tympanic and tender in lower part. Pulse small, weak and 140. Frequent vomiting. Taken to his home and died next day.

CASE 69.—Driver; bullet. Admitted April 20th, 1916, 5½ hours after injury. Entrance wound over McBurney's spot; exit tip of left great trochanter. Facies anxious and drawn, anaemic; much vomiting. Abdomen tense and tender. Pulse 105, small, low tension and volume. No operation. Died next day.

CASE 70.—Sepoy; bullet. Admitted April 24th, 1916, 3½ hours after injury. Entrance wound over McBurney's spot; exit middle left gluteus maximus, both very small. Condition: Great pain, facies very anxious, abdomen tense and very tender; pulse 85, fair volume, but very low tension vomited later. Operation not advised. Died third day; peritonitis and haemorrhage.

CASE 72.—Private; bullet. Admitted April 26th, 1916, 2 hours after injury. Entrance wound to left of posterior superior iliac spine; exit 2 inches below umbilicus, bleeding. Great pain, facies anxious, vomiting. Abdomen slightly tense and tender. Pulse 88 and increasing in rate; restless. Died few hours later.

CASE 74.—Lance-Naick, Punjabis; bullet. Admitted April 25th, 1916, 1½ hours after injury. Entrance wound small, tip of left trochanter; exit 1 inch above pubes, 1 inch to right of middle line. Condition: Facies slightly anxious, much pain; vomited twice. Abdomen somewhat rigid, tender, and slightly tympanic. Pulse 70, full, very fair quality. Operation half an hour later; oblique incision, muscle splitting, good deal of clot and blood in pelvis, and some intestinal contents. Two small holes in small intestine and two in parietal peritoneum over top of bladder. Result: Uninterrupted recovery.

Other lower abdomen cases in Kut were two communicated by Captain M. L. Puri, I.M.S., which both died without operation, one from bleeding and the other from peritonitis; one by Captain W. C. Spackman, I.M.S., in which a small bullet passed through from loin to scrotum. There was great pain, intense desire to micturate, and thirst; the pulse, at first good, rapidly increased in rate, and death occurred in 2½ hours.

There were six cases under the late Major F. C. Lambert, R.A.M.C., in the British Hospital before he so unfortunately contracted his fatal illness. One was operated on and all died; the operated one bled a lot from the splenic vessels. Captain King described three cases. One was a lower abdomen and died with a faecal fistula in eight days; the second was wounded in the epigastrium and died in 24 hours, mostly from haemorrhage; he vomited. The third was a bomb wound over the liver, with no involvement, as far as could be made out, of the intestine; he recovered. None was operated on.

#### *Cases of Wounds above the Transpyloric Plane.*

CASE 86.—Arab, Jan. 1st, 1916. Entrance wound 2 inches below xiphisternum; exit 3 inches above right costal margin. Apparently liver only. No operation; was walking about on third day.

CASE 87.—Arab boy, Feb. 15th, 1916. Entrance wound 2 inches above right costal margin, anterior axillary line; no exit. Pain right side; semi-rigid abdomen. Operation: 3-inch rent in liver, sewn up by thick catgut sutures; good deal of blood in peritoneal cavity, but bleeding was stopping. Recovery. Some trouble with wound in pleura for some time.

CASE 88.—Sepoy. This occurred in India some years ago. The man was hit at a few yards distance on the rifle-range. The bullet entered just about over the surface marking of the pylorus, and the exit was at a corresponding position at the back. There were no untoward symptoms at all, and the man was well in a few days.

*Conclusions.*

1. The mortality in penetrating wounds of the abdomen below the transpyloric plane is very high, about 97 per cent.
2. Slight symptoms or small wounds do not justify conclusion that internal lesion may be slight or harmless. On the contrary, it should be assumed that a penetrating wound means serious damage and probably fatal damage.
3. Laparotomy should be the routine treatment for these cases, provided the condition of the patient is good enough for a major operation.
4. Haemorrhage is the most serious complication of these wounds.
5. Operation should be done at once if serious bleeding be taking place. The pulse is the best guide to this, and needs watching most carefully.
6. It is not worth while, as a rule, to operate if over 12 hours have elapsed since the infliction of the wound.
7. Wounds above the transpyloric plane may sometimes be treated expectantly, especially those apparently involving the liver only.

## THE PHENOMENA OF ANAPHYLAXIS.

By S. WYARD, M.D., B.S.LOND., M.R.C.P.,  
CAPTAIN, R.A.M.C.

THE extended use at the present time of prophylactic and therapeutic injections of antisera brings into especial prominence the condition of anaphylaxis. The liability to the establishment of this condition calls for care in the administration of the sera and for some idea of the mechanism of the reaction in order that rational steps may be taken to minimise or remove the danger that may be apprehended. That anaphylaxis may ensue on suitable treatment with bacterial vaccines has been recognised since the work of Rosenau and Anderson in 1907, but is clinically of little importance on account of the minute quantities of bacterial protein used for vaccination purposes—amounts insufficient to make a toxigenic dose. In the case of diphtheria antitoxin the matter is quite otherwise and is of considerable moment, since there have been many cases reported of severe illness after injection of this serum. A few cases even of death have also been recorded. The question is now especially acute in relation to tetanus, that most terrible disease towards the eradication of which very energetic efforts are at present being directed. And the question arises because a single prophylactic dose of tetanus antitoxin is being given to every man wounded in battle. When, therefore, it is later deemed desirable to give further prophylactic doses of, symptoms of tetanus being manifest, larger therapeutic doses, the medical officer must decide as to the possibility of anaphylaxis following and either trust to luck that no ill-effects are produced or take anti-anaphylactic measures.

The present state of our knowledge—or should it rather be ignorance?—does not allow of any real and satisfactory definition of anaphylaxis. It seems more than possible that the phenomena now included under that head are in reality manifestations of two or more processes. The condition may be provisionally described as one of greatly increased sensitiveness of the animal organism to the introduction of foreign protein, so that injections of the latter in amounts which are innocuous to controls produce in the hypersensitive animals symptoms of varying intensity and even acute death. Such a state of hypersusceptibility may be idiopathic to the individual in a few rare cases, while in others sensitisation may be accidentally effected in ways which are only now coming under suspicion. In addition, many of the clinical symptoms of human disease have been attributed to anaphylaxis, but the term is usually employed to denote the acute shock seen in animal experiments, the serum disease of man, and some diagnostic reactions such as those with tuberculin, mallein, &c., and can at present be applied with any degree of certainty to these conditions alone.

*The Phenomena of Anaphylaxis.*

The Theobald Smith phenomenon is the point from which started the real investigation of this condition. He noticed that guinea-pigs treated with neutral mixtures of diphtheria toxin and antitoxin became subsequently hypersensitive to injections of normal horse-serum, and it was soon shown that the sensitisation was due not to the toxin or antitoxin

but entirely to the normal protein constituents of the serum. From this it was but a short step to demonstrate that anaphylaxis may be effected by any protein substance—e.g., egg-albumen, milk, bacteria, &c. In conformity with the general terminology of immunity, these substances are called antigens. It has further been shown that all antigens are protein in nature, and it is almost conclusively proved that no body other than protein is capable of acting as an antigen.

Turning first to the purely experimental side of the question, it will be well to consider the method by which sensitisation of animals is effected and the results of second injection into such sensitised animals. The first experiments in this direction were those of Flexner, Richet, and one or two others, who showed that rabbits and dogs injected with a foreign serum died after a second injection of a sub-lethal dose of the same serum. The first dose is called the sensitising and the second the toxigenic. These workers used a substance toxic in itself, but even so, it was found that the toxigenic dose caused death in such small amount as failed to do so in untreated animals. It remained for later observers to show that precisely the same effect ensues upon the use of proteins in themselves quite harmless. It has been further found that animals of different species vary greatly in the ease with which they are sensitised—e.g., guinea-pig, horse, and goat fall an easy prey to the condition, rabbits and dogs are less susceptible, and mice almost or completely refractory.

The amount of protein required for a first dose varies within very wide limits, sensitisation having been effected by extremely minute quantities, even as small as 0.000.001 c.c., and there is apparently no limit in the other direction so long as it be not in itself incompatible with the life of the animal. The second or toxigenic dose may likewise vary indefinitely upwards, but the minimal dose is at least 100 to 1000 times larger than that for sensitisation, and is for guinea-pigs some 4 to 5 c.c. These figures refer to such antigens as possess no inherent toxic properties; where the antigen is itself a poison much smaller amounts may be used for the second injection.

The hypersensitive state does not supervene immediately upon the sensitising injection—a certain definite interval must elapse before the animal becomes anaphylactic. In the earlier days of the investigation it was generally thought that this interval varied with the size of the sensitising dose, that the smaller the amount of antigen used the shorter the period required for the full development of the condition and as the amount of the antigen was increased so the period lengthened. More recently, however, it has been shown that no such definite relationship exists and the average time after a moderate-sized first dose is from 12 to 14 days, although after a massive first dose sensitisation may be more or less delayed.

The route by which the foreign protein is introduced into the animal is a matter of some importance. As regards the sensitising dose the usual route is intravenous or subcutaneous injection, but any method will succeed that ensures the penetration of the antigen to the physiological interior of the body. The possibility of effecting this by the alimentary canal seems now fairly certain since it has been shown that protein fed to animals in large quantities is later demonstrable unchanged in the blood. Generally, however, gastric and pancreatic digestion will so alter the constitution of such substances that no sensitisation is possible except in abnormal circumstances where the processes of digestion are interfered with, when it appears that unaltered protein may pass into the large gut, be there absorbed to some extent, and so sensitise the animal. In the case of the toxigenic dose greater variability prevails, and antigen administered by the mouth or per rectum never produces anaphylactic shock,<sup>1</sup> for which purpose parenteral injection must be employed. The most certain methods are intracerebral and intravenous injections, next intramuscular, then intraperitoneal, intrapleural and subcutaneous, and finally intrathecal.<sup>2</sup> The intracerebral route is peculiar in that it

<sup>1</sup> This statement needs modification in view of the fact that the disease produced in some persons by the ingestion of strawberries, eggs, &c., has been attributed to anaphylaxis.

<sup>2</sup> Although this has been often maintained it seems sufficiently doubtful to warrant all care in using this route in human therapy. Huitrel has reported four deaths from anaphylaxis consequent upon intrathecal injection of antimentingococcus serum, and Bewerka and Lisowsky have produced the same effects with normal horse-serum in guinea-pigs. They have thus shown that these animals may be either sensitised or intoxicated by the intrathecal route.

appears less suitable for sensitisation than the other routes; but if the toxigenic dose be given in this way, the shock appears sooner and in greater intensity than in other circumstances.

The anaphylactic reaction resembles all other immunity reactions in its specificity—i.e., specificity is not absolute. An animal sensitised to one particular antigen, in addition to reacting with a second dose of the same substance, may also react to another but closely allied protein but with a quantitative difference—to obtain the same intensity of reaction a much larger quantity of the heterologous substance than of the homologous must be administered. In short, there is much evidence in favour of the view that the toxin responsible for this reaction is in no way specific, but that all antigens give rise to the same poison. The specificity observed is due only and entirely to the specific antigen-antibody complex occurring in each case (*vide infra*). Pointing to the same conclusion is the fact that a non-specific anti-anaphylaxis (refractory period) may be produced by injection of a hypersensitive animal with peptone. It has also been shown that the same animal may be at one and the same time sensitised to a number of different antigens.

The manifestations of anaphylactic shock vary with the species of the animal experimented upon. The essential features are as follows. The onset is sudden and immediate (within a few minutes). The guinea-pig becomes obviously uneasy, with restlessness and sneezing, while the respiratory rhythm increases in rate. This may be followed by discharge of urine and faeces, and the appearance of marked muscular weakness. Later respiration becomes irregular and laboured, inspiration is obviously extremely difficult, and the chest remains permanently expanded, never contracting fully. Death may ensue in a convulsion or by coma, in which the breathing gradually becomes slower and more shallow, until finally it ceases altogether. The condition is evidently due to interference with the respiratory functions. In rabbits symptoms appear after a short interval of a few minutes or more, the animal first showing marked muscular weakness with discharge of urine and faeces. The weakness increases until no voluntary muscular effort is possible but convulsions may occur. Death is due to asthenia. Anaphylactic shock is manifested in dogs first by restlessness, vomiting, and the passage of urine and faeces. General weakness rapidly ensues followed by twitching and laboured and irregular breathing. There is rapid and extreme fall in the blood pressure, and cerebral anaemia causes death. Generalised tremor, great weakness, laboured respiration, and incontinence of urine and faeces are the symptoms of anaphylaxis in horses and goats.

The symptomatology, &c., of human anaphylaxis is discussed in a later paragraph.

The pathology of this condition has been thoroughly worked out by numerous investigators, especially Auer and Lewis, and Pearce and Eisenbrey. It appears due to a toxic substance in the elaboration of which the liver plays some part and its action is probably not central, i.e., upon the central nervous system, but peripheral, upon the nerve endings or the muscles themselves. In guinea-pigs the predominant change is an extreme contraction of the muscles of the bronchioles so that no air can enter the pulmonary alveoli, in consequence of which and the extreme thoracic expansion the lungs are, after death, found blown out and inelastic, with the alveoli distended and many of the septa torn. There are, in addition, more or less numerous visceral hemorrhages. Section of both vagus nerves does not alter these findings, showing that the action is not within the brain or medulla. In dogs the effects are practically limited to the vascular system, and it has been shown that the action is upon the vaso-motor nerve endings, since if these have been previously paralysed no further fall of blood pressure occurs during anaphylactic shock, while a fall produced by anaphylaxis is diminished by the exhibition of drugs which stimulate the muscularis of the blood-vessels.

Little can be said as to the nature of the toxin responsible, since but little is known concerning it. The striking analogy between the manifestations of peptone poisoning and those of anaphylaxis have been pointed out by many, and some have maintained that the latter is due to the action of a peptone. This is not impossible in view of the results obtained by Vaughan and Wheeler with the products of proteolysis—protein split-products; but no real deductions can be made from the phenomena of peptone poisoning in

this connexion owing to the fact that the only samples of peptone available are composite mixtures of many substances, and their composition varies within very wide limits. Rosenau and Anderson came to the conclusion that none of the known antibodies (precipitins, &c.) is responsible for anaphylaxis, but later observations by Doerr and Russ point to the fact that precipitins are in reality a prime factor in the production of the condition.

It is of interest to note that the above method is not the only one by which anaphylaxis can be produced; it is the condition of active anaphylaxis, but the passive installation of the state is also possible. By infusion of a normal animal with the serum of one sensitised the former is rendered sensitive, while it has also been shown that the young of a hypersensitive mother are in the same condition, and that whether the maternal sensitisation be effected before conception or during pregnancy. In such circumstances it does not usually persist for any prolonged period. Transference takes place by means of the placental circulation and not by the milk. Further, Schenk has described inheritance of this condition by the young of normal females impregnated by sensitised males, but this needs confirmation before it can be accepted as fact.

The duration of the anaphylactic period—i.e., the length of time after a sensitising injection during which the animal remains liable to the shock on a second injection—is still in some doubt. Its time of onset, as stated above, is usually 12 to 14 days, and animals have still been found sensitive after as much as three years. It is, therefore, no transitory state and persists for very considerable periods, but whether the intensity of the sensitisation diminishes with age, whether with time it may disappear altogether, and, if so, when such decrease commences and when it is complete, have not yet been worked out. It is thus obviously necessary in dealing with man always to assume the possibility of anaphylaxis resulting if the individual has at any time previously received a dose of antigen capable of rendering him sensitive.

Closely allied to, if not identical with, the phenomena described above is the serum disease of man, which may assume either of three forms. The first to be described was that occurring after a single large dose of serum, and symptoms appear 8 to 12 days after the injection. They are numerous and varied, the commonest being urticaria, often involving a large part of the surface area, sometimes practically all. Other rashes—morbilloform or erythematous—are sometimes, but more rarely, seen. At the same time joint pains are common, and there may be swelling and tenderness of the lymphatic glands associated with the site of injection. Some pyrexia and occasionally slight albuminuria may be associated. The symptoms pass off in from 12 to 48 hours. The second form is the *accelerated* reaction so called because it appears earlier than the above—viz., 4 to 8 days after the second injection. It does not occur after a first injection. The symptoms are similar to those just described, but are more acute, and generally pass off within 12 to 18 hours. As a rule, neither of these forms is of serious import, but now and then may be very severe or even fatal.

The third form—the *immediate* reaction—is the same as that seen in experimental animals. Symptoms supervene within a very short time of the second injection. At present, however, the whole subject of serum disease is in a very unsatisfactory state, and a large amount of work remains to be done upon the subject. Little or nothing is yet known concerning the effect of differences in the size of the first dose or of the second, or of changes in the ratio one to the other. Further, it appears necessary to distinguish between the local effect of the injected antigen and its systemic—anaphylactic—effect. Nothing has yet been done in this direction. Finally, there is the question as to the liability to anaphylaxis after multiple injections, and if it does occur in such cases are the symptoms the same or in any way modified? I am at present engaged upon making observations with a view to throwing light upon these points.

As regards liability to anaphylaxis man appears to occupy an intermediate position in the range of animals, being less susceptible than guinea-pigs, probably less even than dogs and rabbits, but more so than mice. It is of interest, however, to note that the symptoms produced in man approximate closely to those seen in guinea-pigs, and the pathology is probably essentially the same in both cases.

The onset of symptoms is sudden and after but very short delay—generally within half an hour. First appear local pain and tenderness, and the site of injection becomes swollen, red, and hot. The swelling may be very marked, and where the upper arm is used may extend from shoulder to wrist. Irritation with an intense desire to scratch the part may be a prominent symptom. On the other hand, the systemic phenomena may be intense without any or all such local changes. Suppuration never occurs (except infection be effected by faulty technique), and the part becomes normal within 24 to 48 hours. Almost at once the patient complains of difficulty in breathing, the chest becomes expanded and almost rigid, inspiration is particularly impeded, the face may become swollen and congested, the mucous membranes cyanosed. Auscultation of the chest shows the normal vesicular breath sounds replaced by a high-pitched bronchovesicular murmur. Moist sounds are not heard. Extreme urticaria, as in the ordinary form of serum disease, is sometimes seen at the same time. In cases slightly less severe the patient will sit up labouring for breath and racked by a frequent, almost continuous or paroxysmal, dry cough. Relief comes as suddenly as the onset, and in 15 to 30 minutes the patient is to all appearances normal.

As to sensitisation of man it is still impossible to make any definite statements. After considerable doses very many times repeated the anaphylactic state may appear within four or five days, whereas after two or three small doses (4 to 5 c.c. per dose) it may still be absent 28 days after the last. A single injection of 3 to 5 c.c. does not sensitise, and persons receiving massive injections are not, or at all events not always, hypersensitive after six weeks.

#### Theories of Anaphylaxis.

To explain the phenomena of anaphylaxis several theories have been from time to time propounded, but most of them have in one respect or another been found wanting. Adequately to deal with all such theories is impossible in the present circumstances, and, moreover, is not called for by the object in view. Without, however, entering minutely into details of experiments, it is perhaps well to outline the more important of the theories put forward and to indicate wherein they fail.

Gay and Southard, believing that every antigen consisted of two distinct portions, supposed that during the interval between the sensitising dose and the appearance of the hypersensitive state one of these portions—the toxic—was eliminated from the body, while the other—the sensitising—was retained. The latter, acting in some way not yet known upon the body cells, rendered them capable of assimilating the toxic moiety of the antigen, whereas before they were incapable of so doing. In consequence, when the toxigenic dose is administered to a sensitised animal, rapid assimilation of the toxic element by the body cells takes place with resulting anaphylactic shock. As will be seen later, anaphylaxis may occur without active participation of the cells but entirely in the blood, and, further, during the manifestation of the symptoms complement or alexin disappears from the blood, and it has been shown that the complement is an important element in the production of anaphylactic shock. These facts are obviously not accounted for by the theory of Gay and Southard.

A second theory dependent upon the assumption of the existence of two distinct elements in the antigen is that of Besredka. The one he terms "sensibilisinogen," which in the body gives rise to the formation of an antibody, *sensibilisant*. The second element he calls "anti-sensibilisin," which after the first injection is excreted from, or destroyed in, the animal, but after the second injection reacts with the *sensibilisin* with the production of a toxic substance responsible for the subsequent symptoms. This theory becomes untenable in view of the fact that it goes counter to all the known principles of immunity in that it supposes the production of a specific antibody which reacts *not* with its antigen but with another substance altogether.

The above theories received some support when it was found possible to separate by physical means (fractional precipitation, heat, &c.) sensitising and toxic portions from protein substances. These results, however, have not been confirmed, and other workers state that no such preparation is possible, and that the sensitising and toxic molecules are one and the same. On the other hand, Vaughan and Wheeler have effected such a separation by chemical means. But,

even so, the objections enumerated above remain unaffected. Bringing about proteolysis by alkaline alcohol, these two obtained from protein toxic and non-toxic split-products, and therefore supposed that a first injection of antigen leads to a slow lysis by which the non-toxic substance is liberated. This in turn gives rise to the production of an enzyme—a lysin—which, acting with greater rapidity and intensity upon the second injection, liberates comparatively large amounts of the toxic body. Anaphylactic shock results from the action of this latter. The theory is more complete than either of the preceding, since the assumption of a preliminary lysis allows for the part of the complement in the reaction. Friedberger's later theory supplements this and reconciles it more thoroughly with all the facts.

Richel suggests the theory that the first injection of antigen causes the production of a substance, *toxogenin*, and that after a second injection this reacts with the fresh antigen to produce the anaphylactic poison, *apotoxin*. As will be seen immediately, this is but a somewhat crude foreshadowing of Friedberger's second conception, and there is no need to postulate the appearance of a distinct and specific toxogenin since complement and antibody are capable of performing all the reactions attributed to it by Richet. Friedberger's anaphylatoxin too is but Richet's apotoxin under another name.

Bringing anaphylaxis into line with Ehrlich's theory of immunity, Friedberger formerly suggested that the condition was one step towards immunisation. According to Ehrlich, the presence in the body of a foreign protein calls forth the production of side-chains which unite with and neutralise the antigen. These side-chains are formed by and in the cells in excessive numbers which, in the ordinary course of events, are cast off into the general circulation. Friedberger postulates that in certain circumstances the side-chains or receptors remain sessile upon the cells. This appears the more likely if Adami's theory be accepted that the production of receptors is a function of the nucleus from which they pass into the cytoplasm before reaching the blood. It might easily be that for some reason they are held up in the intermediate position. Such a cell would obviously be in a hypersensitive state—the larger number of receptors would attach a greater amount of antigen with a correspondingly greater toxic effect. The same objections, however, are applicable to this theory as to those of Gay and Southard and Besredka—viz., that it does not go far enough and fails to account for all the facts. It is, moreover, doubtful in the light of more recent knowledge whether Ehrlich's theory be the correct explanation of immunity reactions; the weight of evidence appears against it.

Nicolle believes anaphylaxis to be due to the resultant of the action of two substances—an albuminolysin and an albuminocoagulin. Sensitisation causes production of the former out of all proportion to the latter, hence the antigen of the second dose undergoes rapid lysis with the formation of toxic substances. All recent work, however, points to the fact that albuminocoagulin—precipitin—so far from being protective is actually the prime cause of the condition.

Lastly, there remains Friedberger's later theory which, better than any other, reconciles all the known facts and probably approaches nearest to the truth. The blood of an animal showing symptoms of anaphylaxis possesses no, or very little, complement, but that the condition is not due merely to lack of complement is shown by the fact that no modification is effected by the injection of fresh guinea-pig's serum simultaneously with the second dose of antigen, indicating also that complement is fixed in this condition. What is the explanation? Friedberger found that complement is able to form from antigen a toxic body which, injected into a normal animal, gives rise to all the phenomena of anaphylactic shock. But while complement alone is capable of effecting this change to a slight extent, the toxic product appears with far greater rapidity and in far greater quantity if the specific antibody be also present, and this has been confirmed by several other workers, amongst them Thiele and Embleton, who believe that they have traced the direct development of the antibody from normal complement. The toxic substance produced in this manner has been called *anaphylatoxin*. The success of the experiment depends upon three factors—the quantities of complement and antibody, relative to one another and to the quantity of antigen; the time during which the substances are allowed to react; and the temperature at which they are kept. As

regards the first, there is a certain definite range within which (for a given amount of antigen) complement and antibody give rise to anaphylatoxin, but outside which—i.e., if either be in excess or deficient—the toxin does not appear. If the time allowed be insufficient the mixture remains innocuous; if the time be extended beyond a certain limit the mixture becomes innocuous. The disintegration of the antigen proceeds so far that the toxic substances are still further split up to simpler non-toxic compounds. Finally, the lower the temperature the slower the production of anaphylatoxin, the optimum temperature being 37° C. when it is produced in greatest amount and at the greatest rate. Moreover, it is found also that the reaction causes complement fixation—i.e., the complement-antibody-antigen mixture after the formation of anaphylatoxin contains less complement than was put into it, perhaps none at all. Friedberger, therefore, holds that the first injection of an antigen brings about an increase in the antibody present, which, together with the complement normally contained in the blood, immediately reacts with the second dose of antigen, so liberating anaphylatoxin.

That the process is not absolutely so simple as this is shown, however, by an experiment by Pearce and Eisenbrey, who exsanguinated a sensitised dog and replaced its blood by that of a normal dog, while the blood removed from the former was used to transfuse a third (normal) dog previously bled sufficiently to avoid plethora. They thus had a sensitised dog containing normal blood and a normal dog containing sensitised blood. Injection of a toxic dose of antigen into each caused death of the former and no symptoms in the latter, showing that the tissue cells are capable of producing the specific poison. This is only to be expected when it is remembered that the antibody is produced within these cells, and naturally, therefore, they would contain that substance to excess after sensitisation. It is thus evident that, as a rule, both the cells and the serum play their part in the reaction of anaphylaxis.

This theory supplies a simple explanation of all the known phenomena in question and shows their relation to the previously discovered processes of immunity—i.e., accounts for it as a true antigen-antibody reaction. Thus in a normal animal, antibody, if it exists at all, is present only in very small amount. A single dose of antigen, producing first a negative phase, subsequently calls forth a larger amount of antibody than in the untreated animal. These two processes explain the latent, or incubation period, during which no sensitisation is found. At the end of that period antibody is present in such amount that a second injection of antigen is almost at once subjected to lysis with the production of anaphylatoxin as *in vitro*; but in cases where by repeated injections immunity has been conferred the lysis proceeds even more rapidly than above, with the result that the toxic stage of proteolysis is so rapidly passed and the non-toxic stage reached that there is never sufficient toxin in the blood at any one time to cause symptoms.

For the serum disease of man, also, it supplies a simple explanation. It has been observed by numerous workers in connexion with the production of precipitins that there may exist in the blood of an animal both antigen and specific antibody side by side at the same time without precipitation occurring. Applying this fact to the case of a rash, joint pains, &c., developing after a first injection in man, it is known that the antigen in the blood gradually diminishes, while about the eighth day antibody has developed in large quantity; it is, therefore, probable that now both are present together, and when certain favourable concentrations relative to each other are reached reaction will, of course, take place, and the serum disease is the result.

It has also been abundantly shown that antibodies steadily disappear from the blood of an immune animal, but the cells remain more sensitive, and so, when necessary, antibodies are again formed more readily than in non-immune animals. An individual, therefore, who has received one dose of antigen will, if left long enough, eventually lose all antibody, but a second injection will bring about their more rapid production, and again when suitable concentrations of antigen and antibody are reached reaction results, and the reaction occurs earlier than in the case of a first injection but later than in the case of a fully sensitised animal—i.e., the reaction is accelerated but not immediate. Thus it is seen that one only of all the theories put forward comes near to satisfying criticism. Whether it will continue satisfactory as more facts are brought to light, or whether it, too,

in its turn will be found wanting and yield place to yet another, time alone can show. As present it may be accepted provisionally as the best that has been formed.

The theory of bacterial anaphylaxis is precisely similar but does not call for comment in this place.

#### Clinical Considerations.

In spite of the fact that man is less susceptible to anaphylaxis than some other animals the danger of this condition is not one to be treated lightly in administering sera prophylactically or therapeutically. Even though the condition be comparatively mild, no one who has seen a case would desire the experience, still less would he who has once experienced it desire to repeat the experiment. Much work has therefore been done with a view to providing a method by which a sensitised person may be desensitised—i.e., rendered anti-anaphylactic—and, secondly, to curing the condition once it is established. Obviously the former is the more important, and for this the first essential is to recognise when the individual is sensitive. As has been seen, this is at present impossible with any certainty, so until proof to the contrary is forthcoming it must be assumed that anyone who has received one or more injections more than 14 days previously is in this state.

No satisfactory theory has yet been found to explain the development of anti-anaphylaxis, and the methods of producing it are for the present entirely empirical. In the first place, then, it must be thoroughly appreciated that unlike the hypersensitive state the refractory is but transitory and the former sooner or later returns, though perhaps to a somewhat less degree. A massive first dose in many cases requires longer to produce hypersusceptibility than a smaller, but does not cause anti-anaphylaxis as was formerly thought. The administration of lecithin was also said to prevent anaphylaxis, but this has been denied by others. Again, some workers showed that anaesthesia with ether produced it, but this, too, has been later denied, and it seems that its only action is to mask symptoms while it does not prevent death. So much doubt has been cast upon these methods that they cannot be relied upon and are of no practical value in the treatment of man. The following, on the contrary, are not open to this objection and rest upon a firmer basis of experimental proof. The first of these is starvation, as pointed out by Leené and Dreyfus. Hypersensitive animals deprived of all food and allowed only water for four to five days are at the end of that period refractory to a second dose of antigen. While, however, the desired object is thus attained the procedure is obviously unsuitable for clinical application, more especially as other and quite as efficient methods are available.

Vaccination against anaphylaxis may be employed by the injection of small doses of antigen during the incubation period, but to be effective these must be given late in the period, about the seventh, eighth, or ninth day, and have no such protective action if administered early—i.e., about the third, fourth, or fifth day. Once the hypersensitive state is established no use can be made of this method.

If 5 to 10 c.c. of the antigen be given into the rectum, this having first been thoroughly cleaned out, the individual is rendered refractory from 10 to 12 hours later, and further subcutaneous injections may be carried out with impunity. The antigen is very slowly absorbed when given by this route, which is probably the reason for the subsequent desensitisation, it having also been found that if the antigen be administered subcutaneously in such a manner as to ensure an extremely slow entry—e.g., after the fashion of a subcutaneous saline infusion—very large amounts may be tolerated, which if given rapidly in the usual way would certainly cause death. Both these methods present certain drawbacks in that they are inconvenient and occupy a comparatively long time. Finally there are two methods similar in principle but differing slightly in detail by which anti-anaphylaxis may be certainly effected with but very little trouble. In considering the phenomena of hypersusceptibility it was seen that the effective toxicogenic dose was very considerably greater than the sensitising—that there was a definite minimum below which the antigen failed to elicit anaphylactic shock. This fact is here made use of, for by the injection of such a subminimal dose the individual is thereafter rendered refractory for a time, during which further and even large doses may be safely given. In man sensitisation rarely if ever reaches such intensity as to cause reaction with 1 c.c. of blood serum, so that in the use of

diphtheria or tetanus antitoxin, if it be considered unsafe to inject a large dose at once, 0·5 to 1·0 c.c. may be used as a preliminary injection, followed five or six hours later by any further dose that may be considered necessary. Should even greater rapidity be desirable, such a preliminary dose may be followed in 5 or 10 minutes by a larger and every 5 minutes or so afterwards by steadily increasing amounts whereby in a very short time enormous doses may be given and without risk of anaphylactic shock. In the case of tetanus antitoxin where prophylactic doses are given these are practically all innocuous. The amount of serum actually employed varies from 3 to 5 c.c., according to the concentration of the sample. An interval of anything up to five weeks between two such doses will never give rise to symptoms. About the sixth week, however, hypersensitivity may appear. These remarks do not, of course, refer to those patients who have received previous massive injections—e.g., for declared tetanus or who require subsequent massive injections for therapeutic purposes. In such circumstances every precaution must be taken as indicated above.

It is obvious that nothing can be done to guard against the reaction after a first injection, as the individual gives no indication of his increased sensitiveness.

If the foregoing facts be borne in mind and the proper steps taken to avoid anaphylactic shock, there should rarely be any call for the treatment of that condition. Should it arise, however, every effort must, of course, be made to afford immediate relief. In mild cases the attack may be over before treatment can be applied; if more severe the exhibition of certain drugs may prove of service: such are atropine, adrenalin, chloral hydrate, and pure oxygen. In using either of the first two substances, subcutaneous injection is far too slow a method to be of use; they must be given intramuscularly or intravenously. In cases of still greater severity artificial respiration may be necessary and may alone succeed in tiding the patient over the period of shock, but is better used in association with one or other of the above-mentioned drugs. In a few instances of the utmost gravity no efforts will be of any avail, and death ensues. As regards the local signs, treatment is rarely called for. Much pain and swelling find relief in a hot fomentation, while irritation is allayed by moistening the surface of the part with 1 in 60 solution of carbolic acid.

#### Summary.

In conclusion it may be stated: (1) that man, like other animals, is liable to become anaphylactic; (2) that no certain indications of the existence of the state in him are yet available; (3) that there are certain methods by which the danger may be simply and altogether avoided; (4) that anaphylactic shock in man is very rarely of great severity; (5) that it can almost always be cut short and the patient restored by suitable therapeutic measures; and (6) that fear of this condition can never justify failure to employ antitoxic sera both prophylactically and therapeutically in those cases where it is indicated.

## TRAUMATIC RUPTURE OF THE JEJUNUM; OPERATION; RECOVERY.

By W. SAMPSON HANDLEY, M.S. LOND., F.R.C.S. ENG.,  
SURGEON TO THE MIDDLESEX HOSPITAL.

THE following case of traumatic rupture of the jejunum has points of interest in addition to its fortunate issue.

Miss —, aged about 25, while crossing a street, was knocked down by a motor bus, and one of the front wheels was said to have passed right over her abdomen. The patient herself could not remember anything of the accident. She was admitted to the Middlesex Hospital immediately in a state of profound shock. One or two fractured ribs were present on the left side, apparently the eighth and ninth. There was no visible bruising of the abdomen. The patient was rather pale, but not bloodless, the pulse slow, about 70, and very small, and the extremities rather cold. Her facial appearance was that of intense pain. The abdomen was absolutely and uniformly rigid all over. There were no areas of dullness, no loss of liver resonance, and the only localising sign was the fracture of the ribs. It was evident that some serious internal injury was present, most probably a rupture of the spleen, and immediate operation was undertaken. An incision was made in the left semilunar line. Owing to the difficulties presented by a long thorax this was subsequently

extended obliquely upwards and inwards across the rectus muscle and then upwards in the middle line to the ensiform cartilage, thus assuming a bayonet shape. On opening the abdomen a certain amount of fluid came out, but there was no large amount of haemorrhage. No gas escaped, but there was a little fluid which suggested intestinal contents. The spleen was exposed with much difficulty, since it was small in size and situated high up in the arch of the diaphragm. There was some bleeding from its pedicle, but the large vessels were evidently uninjured. The small intestine was now investigated, beginning at the duodeno-jejunal flexure. Almost immediately, at a point six inches below this flexure, the small intestine was found to be torn completely across. The tear was a fairly clean one, not extending beyond the intestinal edge of the mesentery, and haemorrhage had ceased.

My first intention was to resect the bowel, but upon consideration there seemed no reason for subjecting the patient to this additional shock. I decided simply to join the bowel by making an end-to-end anastomosis; this was quickly done. A piece of gauze was packed down to the bleeding area near the spleen, and the incision was closed after washing out the abdomen in every part with a large quantity of saline and introducing a pelvic drainage-tube just above the pubes. A considerable quantity of intestinal contents was found to be present in the pelvis, and but for the lavage and drainage the patient would probably have had subsequent peritonitis and intestinal obstruction. At the end of the operation, which occupied about half an hour, the pulse was about 120.

The after-treatment included starvation diet for some days. During this period nutrition was maintained by two subcutaneous injections of normal horse serum. The day after the operation the patient vomited several times; no flatus had been passed and there seemed to be threatened intestinal obstruction. These symptoms, however, passed off upon the administration of eserine in doses of 1/40th of a grain subcutaneously three times a day. The eserine was supplemented by the use of injections of pituitary extract. From the fourth day the patient's condition gave rise to no anxiety, and she made a complete and rapid recovery. Solid food was first permitted about a fortnight after the operation.

I believe the favourable result of the case is largely to be attributed to my abstention from resection. The patient was in a state of deep shock, and it seemed very probable that the resection would have proved too much for her powers of resistance. It seems likely that the wheel of the bus did not pass completely over the abdomen, but that it crushed in the left side of the chest, and was arrested in the neighbourhood of the vertebral column. In its course it must have stretched and pressed backwards into the left kidney pouch the highest portion of the jejunum. Thus the transverse tear across the bowel was produced by tension and not by crushing. This, at any rate, was the conclusion at which I arrived.

A similar successful case of traumatic rupture of the jejunum near the duodeno-jejunal flexure was recorded by Mr. R. P. Rowlands.<sup>1</sup> In Mr. Rowlands's case there was a very large laceration 2½ inches long running obliquely across the dilated oedematous jejunum about a foot below the duodeno-jejunal flexure. The lacerated bowel was lying far back in the left flank near the spleen. The tear was closed by a two-layer continuous suture. The mesenteric border of the bowel had not been divided.

Berry and Giuseppi<sup>2</sup> found the mortality of rupture of the intestine from contusion in the records of ten London hospitals previous to 1908 to be 80 per cent. (67 deaths in 84 cases). Siegel's statistics, quoted by Rowlands, emphasise the importance of early operation.

Cases operated upon in first—	Mortality.
4 hours ... ... ... ...	15·2 per cent.
5-8 " " " "	44·4 "
9-12 " " " "	63·6 "
Later ... ... ... ...	70 "

The main interest of my own case is, I think, that it shows the possibility, and suggests the advisability, of avoiding resection even when the bowel has been completely torn across.

## Reviews and Notices of Books.

### An Introduction to Neurology.

By C. JUDSON HERRICK, Professor of Neurology in the University of Chicago. Illustrated. London and Philadelphia: W. B. Saunders Company. 1916. Pp. 360. Price 7s. 6d. net.

WHEN any branch of science has developed sufficiently to justify the appearance of a 350-page closely printed volume as a mere "introduction" to the subject, it may fairly be regarded as a subject whose field is wide and widening, and whose study is difficult and calls for application. The author's remark that neurology is a science whose study is intrinsically difficult if the student is to advance beyond superficial phases is not only the bare truth, it also explains the importance of grasping fundamental principles of nervous structure and function as a preliminary essential to their application in any of the subdivisions of science—medicine, psychology, sociology, education—where knowledge of the nervous system in man is required.

Professor Herrick's book comprises a series of chapters on (1) the structural elements of the nervous system and the phenomena of nervous activity; (2) the special anatomy of the various functional systems, such as those of the spinal cord, medulla, cerebellum, vestibular apparatus, auditory apparatus, visual apparatus, visceral apparatus, and so on, and the physiology of the same; and (3) the structure and functions of the cerebral cortex. Each of the chapters concludes with a summary of its contents and with a short bibliography of the more important papers bearing on its subject. In addition, there is a full index and glossary at the end of the volume. The illustrations are clear and accurate.

A book like this requires to be studied. It is full of information, both anatomical and physiological, and its instructiveness is enhanced both by frequent reference to clinical data and by the use that is made of comparative anatomy and, to a less extent, comparative physiology. The author is more content to state various hypotheses that hold the field in regard to any particular neurological problem than to adjudicate between them. The paragraphs devoted to the sympathetic system do not appear to give as clear a view of its physiology as might be desired, and there is little attempt to elaborate the niceties of cerebellar function. It is easy, however, to suggest additions when the subject is so large, while the author expressly eschews details in his desire to formulate general principles. On the whole the book is stronger on the anatomical than on the physiological side. Its merits are many, and it will be found to provide the student and the physician with an excellent summary of modern teaching, as based on recent research into the anatomy and physiology of the most complex system of the human body.

### A Practical Guide to X Rays, Electro-therapeutics, and Radium Therapy.

By A. E. WALTER, M.R.O.S., L.R.C.P. Lond., Major, Indian Medical Service, &c. Calcutta: Thacker, Spink, and Co. 1916. Pp. 234. Price 10s. 6d. net.

IN writing this book the author has attempted to cover the whole field as stated in the title and to deal also with elementary electricity and the use and management of machinery for the production of electric power. He has included descriptions of nearly every known X ray apparatus as well as those used in electro-therapeutics. It is evident that we cannot look for any extended dissertation on any one subject, seeing that the whole is comprised in a volume of moderate dimensions. Under ordinary circumstances it would be a fair criticism that the author has attempted too much within the space he has allowed himself, but we have to remember that this book is mainly intended for those whose duty carries them to the outposts of Empire where information and appliances are not easily obtained, and where at times both ingenuity and resource are tested to the utmost. Looked at in this light the book fulfils its function well, and it will be of the utmost service to those for whom it has been written. Major Walter has the art of giving information clearly, and with a degree of conciseness that is seldom found, and for this reason it is a

book that the beginner, at least, cannot afford to read hurriedly, so closely are the facts packed together. It may be said that when the contents of this volume have been mastered the student will have gained a very fair all-round knowledge of X rays and electricity in their medical applications, and will be in a position not only to do good work but to appreciate the writings of the more advanced workers.

### Cleft Palate and Hare Lip.

By Sir W. ARBUTHNOT LANE, Bart., M.S. Lond., F.R.C.S. Eng., Surgeon to Guy's Hospital and to the Hospital for Sick Children, Great Ormond-street. Third edition. London: Adlard and Son. 1916. Pp. 102. Price 10s.

To this edition of his short but well-known work the author has made some additions, and especially he gives now an account of those measures which are requisite in many cases to render the condition of the patient as normal as possible after operation. The operation for cleft palate devised by the late Mr. Davies-Colley and now used extensively throughout the surgical profession was largely made known by Sir Arbuthnot Lane. The case for this operation is well put forward, but the relative merits of this and the Langenbeck operation are not discussed. Numerous excellent diagrams explain very clearly the operative procedures. A chapter on the speech training after palate operations has been contributed by Mr. Cortlandt MacMahon; this contains an account of the methods which should be adopted to remedy the remaining defects. The dental treatment of cleft palate is described by Mr. W. Warwick James, and an account is given of the prosthetic appliances which may be required.

### Roentgenographic Diagnosis of Dental Infection in Systemic Diseases.

By SINCLAIR TOUSEY, A.M., M.D. Illustrated. New York: Paul B. Hoeber. Pp. 75. Price \$1.50.

THE aim of the author is to show that teeth which may appear clinically healthy are frequently the foci of infection, and he points out that these foci can only be reliably diagnosed by means of the X rays. The book is well illustrated with skiagrams of the teeth obtained by means of films. Skiagrams obtained in the ordinary way on plates are frequently quite useless as a means of diagnosis, the film being the only reliable method, and the author has done good service by showing the value of this method in X raying the teeth. For the treatment of pyorrhoea alveolaris he advocates the use of X rays and high-frequency currents, but the cases he gives are not convincing. He shows skiagrams of the dental condition in a long series of diseases, and from his text we are led to infer that he considers the dental condition as the cause; but because two conditions are associated they are not necessarily related as cause and effect. The main value of the book is in the illustrations.

### RECENT BOOKS ON CHEMISTRY.

*A System of Physical Chemistry.* By WILLIAM C. McC. LEWIS, M.A. R.U.I., D.Sc. Liverp. With diagrams. London: Longmans, Green, and Co. 1916. In two volumes. Vol. I., pp. 523; Vol. II., pp. 552. Price 9s. each volume.—These two volumes serve to illustrate the important advances in our learning which have been made during recent years as the result of the joint study of chemistry and physics. The author has given his subject a very comprehensive handling and has included in his review some of the most recent theories and their adaptations, while his references to literature are copious and valuable. Indeed, this systematic work is by no means elementary in aim and scope, and the reader is advised to familiarise himself with the broad outlines of the subject before taking up the later problems. In any case he will not read the book profitably without some knowledge of both physics and chemistry, and he will require a mathematical faculty. The book is a valuable addition to the library.

*A Text-book of Organic Chemistry for Students of Medicine and Biology.* By E. V. MCCOLLUM, Ph.D. New York: The Macmillan Company. 1916. Pp. 426. Price 10s. net.—The author expresses the hope that this book will "serve as a satisfactory text for students of medicine and others who can give but a semester to this subject, and whose interest

is in some field of biology." This is a frank acknowledgment of the limitations of the book, but it is undoubtedly useful to have a compilation more or less confined to the description of those organic compounds which are concerned in biological processes. These compounds form a large group, and so considerable ground in organic chemistry is covered. The author very properly emphasises the importance of structure and constitution, and altogether presents his subject logically. The book is a valuable preparation for the intelligent consideration of physiological questions.

*A Method for the Identification of Pure Organic Compounds.* Vol. II. By SAMUEL PARSONS MULLIKEN, Ph.D. London : Chapman and Hall, Limited ; New York : John Wiley and Sons, Inc. 1916. Pp. 327. Price 21s. net.—We reviewed at some length in THE LANCET of June 18th, 1904, the first volume of this series, which embodied the classified descriptions of about 2300 of the more important compounds of carbon with hydrogen and with hydrogen and oxygen. This second volume is no less thorough in its breadth of treatment, containing classified descriptions of about 4000 of the more important compounds of carbon with the elements nitrogen, hydrogen, and oxygen. The former volume thus deals with aldehydes, carbohydrates, acids, phenol derivatives, esters, ketones, alcohols, and hydrocarbons, while the present volume relates to organic bases, alkaloids, amino-bodies, nitro-groups, and so forth. It provides a systematic analytical procedure based on physical properties and chemical reaction, and amounts to a dictionary of physical constants and chemical characteristics or tests of the compounds coming under the order set out by the author. This compilation must have entailed an enormous amount of work, including the careful verification and revision of the proofs, and it has all been admirably done. It is hardly necessary to point out what a valuable work of reference this will prove to be to a very large section of scientific investigators.

*Organic Chemistry.* By VICTOR VON RICHTER. Vol. I., Chemistry of the Aliphatic Series. Newly translated and revised from the German edition (after Professor Edgar F. Smith's third American edition) by PERCY E. SPIELMANN, Ph.D., B.Sc., F.I.C., A.R.C.Sc. London : Kegan Paul, Trench, Trübner, and Co., Limited. 1915. Pp. 720. Price 21s. net.—The publishers explain that a year's delay has occurred in the production of this volume owing to Dr. Spielmann's employment on important work connected with explosives for the Government. This is the first time, we believe, that the German original has been directly translated in this country, previous translations into English having been done by an American author, Edgar F. Smith, professor of chemistry in the University of Pennsylvania. The present volume is a translation of the latest edition of the German original. The references to German literature (largely the "Berichte der deutschen chemischen Gesellschaft" and Liebig's "Annalen der Chemie") are very copious, but tell us only the number of the journals without giving their dates. It is thus difficult to see at once whether these references are recent, although a general inspection of the subject-matter shows that the book has been brought well up to date. The index is very complete, amounting to 40 pages in close small type, thus showing a considerable extension on previous editions. Within its compass there is no work that we know of which gives such an exhaustive list of carbon compounds, and while the descriptions are necessarily brief it is not easy to find omissions. The reader requiring fuller information has references provided. The following paragraph (page 576) on the C-alkylated barbituric acids has evidently been overlooked in the reading of the proof-sheets : "These compounds have been minutely studied on account of some of their number acting as *valuable saporifics*—e.g., C-diethyl barbituric acid (veronal) and C-dipropyl barbituric acid."

*Analytical Chemistry.* Based on the German text of F. P. TREADWELL, Ph.D. Translated and revised by WILLIAM T. HALL, S.B. Vol. I. : Qualitative Analysis. Fourth English, after the eighth German, edition. New York : John Wiley and Sons, Inc. ; London : Chapman and Hall, Limited. 1916. Pp. 538. Price 12s. 6d. net.—This book well illustrates the application of new principles to the inter-

actions concerned in analytical chemistry. The theoretical side of the subject, that is to say, has been developed, and so we find the mass action principle discussed, the ionisation theory, and the theory of oxidation and reduction. The reactions throughout are expressed in equations with the ion signs, and when reversible the sign of the double arrow  $\rightleftharpoons$  is used in place of the equality sign =. The materials of the book are well chosen and the descriptions are up to date, while the selection of tests is clearly based on a practical acquaintance with satisfactory procedure. There is an obvious knowledge of the fallacies which creep into analytical literature. While the author introduces much that is novel, he adopts improvements on the well-known classical tests, bringing them into a line with new facilities and improved reagents. As an example of a refinement in the work of chemical detection may be mentioned the exquisite test for the presence of mercury vapour in the air. This test is said to be so extremely sensitive that a blank test performed in places where work with mercury has been performed will often show the presence of this element in the atmosphere. It depends upon the absorption of mercury by gold-leaf placed in a tube through which the air is aspirated. The leaf is then placed in an exhausted tube previously washed out with hydrogen. An electric discharge is next passed through the tube, and the characteristic green line in the spectrum is distinctly visible in the presence of the merest trace of mercury. The test is still more sensitive when the gold-leaf is warmed.

#### JOURNALS.

*Journal of Physiology.* Edited by J. N. Langley, Sc.D., F.R.S. Cambridge University Press. 1916. Vol. L., No. 5, pp. 265-344, price 6s. ; No. 6, pp. 345-390, price 3s. ; No. 7, pp. 391-458, price 5s.—On Anaphylactic Effects as shown in Perfusion Experiments on the Excised Heart, by A. S. Leyton, H. G. Leyton, and S. C. M. Sowton. Alien serum was perfused through excised hearts, the muscle of which had been sensitised by a previous injection of a small dose of an alien serum. The results do not lend themselves to summary.—Variations in the Blood Sugar in Health, by George Graham. The sugar was investigated by a modification of Bang's method in the author's blood at intervals for over one year, and it was found to vary between 0.1 and 0.13 per cent. The ingestion of 100 gm. of glucose produced a sudden rise in the blood sugar, apparent 10 minutes later and usually reaching its maximum in 20 minutes, and falling to its original level in one to one and a half hours. Under conditions which cause fatigue the blood sugar rose to a greater height and took three to four hours to fall to its original level. The author suggests that in the normal rise the "extra" sugar is on its way to the muscles and other storehouses, and that the rise which takes place in fatigue is due to slight failure of the muscles and other storehouses.—The Regulation of Excretion of Water by the Kidneys, by J. S. Haldane and J. G. Priestley. The authors find that the enormous diuresis caused by ingestion of water is not dependent on general dilution of the blood with liquid and that the diminished excretion of urine following great sweating is not dependent on the general concentration of the blood, although some general concentration may occur.—The Biological Mechanism of Growth, by W. Cramer. The author continues his researches on growth as manifested in transplantation of neoplasms.—Observations on Denerivated Muscle, by J. N. Langley. The atrophy of denervated muscle is shown to be not merely a disuse atrophy due to the absence of contraction.—The Recovery of Conductivity and of Excitability in Nerve, by E. D. Adrian. The experiments show that the recovery of conductivity is probably complete at the moment when recovery of excitability is complete.—The Function of Hæmoglobin in Invertebrates, with Special Reference to Planorbis and Chironomus Larvae, by I. Leitch. The author finds that in these larvae the function of hæmoglobin consists in making available, by its power of binding oxygen chemically, a quantity of oxygen sufficient for the needs of the animals at oxygen tension so low that the necessary amount is not supplied by physical solution. The experiments were conducted

under the direction of Professor Krogh in Copenhagen.—The Effects on Higher Animals of the Sterilisation of the Inhabited Medium, the Air and the Food, by I. Kianzin. Much difference of opinion prevails as to the effect of micro-organisms on higher animal life. The author has been engaged investigating this subject at intervals from 1894. He gives a summary of other workers in the same or similar fields. Observations—micro-organisms being excluded, sometimes from the air or food, or both—have been made by many other observers on guinea-pigs, tadpoles, and chickens obtained from sterilised eggs. Some of the observers found that the absence or partial absence of micro-organisms has a deleterious effect on nutrition. From his own observations on mammals of the effect on the assimilation and dissimilation of nitrogen, on sterilising the air and food supplied to them, the author found that there was a decrease of nitrogen assimilation and that death soon followed, varying in different animals. The more fatal results in his observations the author attributes to a more complete absence of micro-organisms in the air, and concludes that the micro-organisms of air are essential to life. Not only is there an imperfect assimilation of N compounds, but there is a large increase of leucomaines. —Slow Waves of Contraction in Muscle, by J. N. Langley. As long ago as 1858 Schiff observed that on mechanical stimulation of mammalian muscle a short time after death a slow wave of contraction proceeded from each side of the point struck, and on arriving at the end of the muscle was reflected backward. In the meantime another wave had been set up at the stimulated spot and crossed the reflected wave, which was in its turn reflected. Since then it has been found that slow waves of contraction occur in normal muscle. It has been suggested that the contraction is a sarcoplasic and not a fibrillar contraction. So far it does not appear that such waves due to chemical stimulation have been described. The author has made observations especially upon the effects of sodium sulphocyanide, which produces waves with considerable constancy. They can be set up in the nerve-free ends of the sartorius of the frog as well as in the middle region, and they are not prevented by curarisation. The ease with which they can be set up by direct application of 2 per cent. sodium sulphocyanide in Ringer's fluid varies with different muscles. They are readily obtained in the leg muscles. Other drugs, such as eserine salicylate, were also used.—The Action of Sodium Sulphocyanide on Muscle, by J. N. Langley. The author confirms in general the observation that sodium sulphocyanide (2 per cent.) applied to a frog's gastrocnemius muscle causes strong primary contraction, followed by contracture and by frequent twitchings. The effects, however, vary with the condition of the muscle itself and also with individual muscles. Some of the effects are prevented by curari, others not. The action of the drug in some respects resembles that of guanidine, and in others that of nicotine. Guanidine, when applied to a small spot of a muscle, often causes twitching, not only where it is applied, but at some part of the muscle more or less remote from this, best in submaxillary and gracilis. Reasons are given for thinking that this widespread of contraction is due to axon reflexes, and not to fluid.—The Influence of the Vagus on Pancreatic Secretion (No. 2), by G. V. Anrep. This is a supplement to a previous paper,<sup>1</sup> already referred to in THE LANCET. In a decerebrate dog stimulation of the peripheral end of the vagus at first is generally without effect on the pancreatic secretion; but there follows after a long latent period a secretion which reaches its maximum only after the end of stimulation. With repetition of the stimulation the flow of juice may start within a few seconds after stimulation is begun. The gland would seem to be in a state of inhibition during the long latent period—all secretory action of the pancreas is blocked, the secretory capacity of the gland is diminished. The vagus exerts the same inhibitory action on a secretion obtained by injecting HCl into the duodenum, or secretin into the veins. The author finds that:—1. Stimulation of the splanchnics or obstruction of the aorta causes a diminution of the pancreatic secretion—the former may even cause complete arrest. If the secretion is rapid, the strongest stimulation of the splanchnic nerve causes only a slowing, never an arrest. Aortic compression is more effective, and it finally stops the secretion in every case. 2. The vagus has no vaso-constrictor.

nor vaso-dilator fibres to the pancreas. 3. Stimulation of the vagus causes a dilatation of the pancreas; when secretion begins the dilatation finishes, and the gland comes to its normal volume. 4. The dilatation is abolished by atropine when secretion is abolished. 5. Vagal "inhibition" of the pancreatic secretion is accompanied by a dilatation of the gland strictly coinciding with the time of this inhibition. 6. The dilatation is the result of a constriction of the pancreatic ducts or of a retention of the juice in the glandular cells which secrete it.—The Direct and Indirect Effects of X rays on the Thymus Gland and Reproductive Organs of White Rats, by Evelyn E. Hewer. As both thymus and reproductive organs are affected by X rays it was expected that irradiation of one organ might bring some light to the question of its relation to the other organ. We can only quote a few of the author's results. Direct irradiation of the thymus does not determine the appearance of Hassall's corpuscles unless the gonads are simultaneously treated. Irradiation of the thymus only causes slight degeneration of the male gonads and delay of sexual maturity, but no alteration in the female. As to irradiation of the male gonads, degeneration occurs and the affected cells are set free in the lumen of the tubules by desquamation. Regeneration is possible, depending on the age of the animal and the total dose of X rays. If the spermatogonia are all destroyed no regeneration can occur. Hassall's corpuscles always appear, but disappear in time. Excessive vascularisation of the suprarenal and hypertrophy of the islands of Langerhans sometimes occurs. A very weak total dose accelerates sexual development. Irradiation of female gonads shows that young ova are more resistant than older, while the corpora lutea become abnormally vascular and the hypertrophy of the interstitial gland is constant and persists even after apparent regeneration of the ovary.

*Journal of Cancer Research.* Baltimore: Williams and Wilkins Company. Price 23s. per annum.—In the last issue of this quarterly magazine, dated October, 1916, but not published till quite recently, Professor G. N. Calkins continues his studies of the effects of cancer tissue, embryonic tissue, and normal tissue on the vitality of protozoa, using *Didinium nasutum* again as indicator.—Dr. L. Loeb and Dr. M. S. Fleisher describe in great detail transplantations of benign tumours of the rat, mostly adenofibromata.—The number includes an account of a case of primary carcinoma of the ureter, by Dr. E. C. Schmidt, in which the 19 cases previously recorded in the literature are analysed. The contribution to the question of cancer heredity by Miss M. Slye, entitled "The Inheritance of Spontaneous Tumours of Specific Organs and of Specific Types in Mice," is important. Miss Slye concludes that the predisposition to develop cancer of certain organs is inheritable. Genealogical trees are given of a number of strains in which cancer of the lungs or liver, for example, occurs with abnormal frequency. It is rather disconcerting, however, to find that in the cases of the lung and the liver metastatic tumours are grouped with primary growth in calculating the percentage frequency of deaths from cancer in these strains. Even without the metastatic growths the tendency to aggregation of primary cancer of specific organs in single strains is evident, but naturally not to the same extent.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—A quarterly meeting of the Council was held on Jan. 11th, Sir William Watson Cheyne, the President, being in the chair. The best thanks of the Council were given to Dr. W. Colin Mackenzie, of Melbourne, Australia, for presenting to the College his collection of marsupial and monotreme material used by him for the purpose of an investigation, carried out in the Museum workrooms, relating to the anatomy and physiology of the animals which are native to Australia. In reply to a letter from the War Office the Council stated the arrangements which they considered might be made for placing on exhibition a selection of pathological specimens from military sources of which the College are taking care for the War Office. New by-laws were ordained for giving Fellows resident abroad facilities for voting for members of Council, and steps are about to be taken to submit them to the Crown for approval. Mr. F. F. Burghard was appointed a member of the Committee of Reference.

# THE LANCET.

LONDON: SATURDAY, JANUARY 20, 1917.

## Mobilisation of the Medical Profession.

FROM previous articles which have appeared in these columns it is well known to our readers that a very important and critical point has been reached in the position of the medical profession with regard to the supply of doctors for the Navy and Army, principally, of course, with regard to the supply for the latter service. The methods under discussion to arrive at a satisfactory scheme have been alluded to by the medical correspondent of the *Times*. While everyone knows that debates of an important character have been taking place in regard to the mobilisation of doctors, to-day we are able to announce that representatives of the Central Medical War Committee, of the Committee of Reference of the English Royal Colleges of Physicians and Surgeons, and of the Scottish Medical Service Emergency Committee are seeking an early interview with the Director of Public Services, having submitted a memorandum on the many problems involved.

The main question at issue is whether the medical profession should or should not mobilise itself as a separate entity under the Director of National Service, this being an immediate response to the statement of the Prime Minister, who, when speaking of the whole population, intimated that, where voluntary mobilisation did not fulfil expectations, compulsory powers would have to be sought. Put quite crudely, Mr. LLOYD GEORGE's intimation was that, speaking of the community at large, where volunteer services were found to be inadequate, general conscription would be employed, so as to ensure that every man in the country, during the critical position in which the State is now placed, should give his help how, when, and where he is best qualified to do so. For it is common knowledge that at the present moment there is not only a large number of people who are shirking their responsibilities, but that there is a still larger number whose potentialities for good are not properly utilised, and who may be doing, as well as they can, things for which they are unfitted, while activities for which they have real qualifications are neglected or remain in other hands. We must all feel that, as far as the medical profession is concerned, we want to be free from such reproach, for economy of labour is necessary for our national welfare. The country is absolutely sound in its resolve to proceed to the unquestioned and commanding success which, though so long delayed, has become inevitable by the trend of naval

and military affairs. This resolve is quite general and unfaltering, but the measure of delay in the accomplishment of our great aims is the measure of the widespread trouble in which we all abide, as well as of the incalculable misery to those who are under the heel of the invader. The shortest possible term must be put to this position, and while the one and only argument that will prevail is the possession by our cause of incomparable fighting forces, the duty before all sections of the population is to keep those forces at a standard of perfection. When the medical profession is told that doctors are and will be required for the army, we medical men know that in some way or other they must be found.

The medical profession is the one section of the community which is already equipped for its work. The duty of a medical man in times of war, as in times of peace, is primarily to prevent disease or injury and, secondarily, to remedy disease or injury. It is not a question of the dyer making explosives, of the bicycle or the piano manufactory being employed for the manufacture of war material, of the governess becoming a milkmaid, or of the judge becoming a chemist. The doctor who practised before the war is ready-made in all essentials to be the doctor during the war, but if a full value is to be got out of his specialised services, and if the limited supply of personnel is to meet a practically unlimited demand, the greatest possible economy must be exercised. Square pegs must be put into square holes, and overlapping must be guarded against. Moreover, offers of part-time assistance must not be despised as partial patriotism; and especially must this view be discountenanced where it can be proved that, not only would the part-time service enable others to offer whole-time service, but that the rest of the time of the partly employed doctor with the troops could be utilised for the good of the State in a civilian capacity. To our mind all this means one thing only—it means that any organisation of the medical profession to meet the emergencies of the situation should be carried out under the assistance and guidance of members of that profession. They are familiar with the possibilities and limitations of medicine and with the characteristics of the help that can be offered by individual medical practitioners; they are also aware of the amount of work which must be discharged by medical men to keep the civilian population in health. We are all in this war—man, woman, and child; that is what the Prime Minister meant in his reference to the determination to seek compulsory powers with regard to the whole of the community if voluntary mobilisation failed. But by as much as we are all in this war, by so much is it necessary that the health of us all should be maintained, so that our general efficiency for attack or resistance should remain at the high level that can be only expected from a physically sound people. If the medical profession is mobilised as a separate entity under the Director of National Service, but in accordance with its own experience and knowledge, the three statutory committees now existing—namely, the Central Medical War Committee, the Committee of

Reference of the English Royal Colleges, and the Scottish Medical Service Emergency Committee—would form the organisation necessary to carry out the work, allowing for modifications which it would not be difficult to bring about. The task before these Committees, however strengthened, must be difficult, but they possess the information and experience. More doctors are required for the Army, and at the same time the number of men discharged as disabled grows, and the medical care of the munition workers increases in urgency. The number of doctors of military age who can possibly be spared from their districts is now becoming small. These facts indicate that there must not be delay in meeting the situation by a definite line of action.

### Tetanus and the Use of Protective Serum.

TETANUS is no longer a frequent complication of gunshot wounds, but it is still, when it occurs, so likely to be fatal and so horribly painful to the patient that no efforts can be too great to get rid of the disease altogether. In the home military hospitals during the year ending July 31st, 1916, we know from Sir DAVID BRUCE's analysis which we published on Dec. 2nd last, that 195 cases of tetanus were received, of which 96 died. The number received varied greatly from month to month, roughly in proportion to the total number of gunshot wounds. No obvious falling off occurred during the year, and there is at the present moment some evidence to hand of an increasing number of cases, some of them being of the fulminant variety so tragically common in the ranks of all the combatants during the early months of the war.

As a prophylactic injection of protective serum is now a routine measure at the front in every case of gunshot wound, it is evident that the protection afforded by a single injection is not complete. The official Memorandum on Tetanus<sup>1</sup> advised the repetition of the serum injection in all septic cases at intervals of seven days in order to keep up the protection, but Sir DAVID BRUCE commented in his analysis on the fact that there was no record of the employment of serum as a prophylactic in the home military hospitals. Possibly the fear of harmful effects from repeated injections of horse serum may have acted as a deterrent, for "serum disease," as it may still conveniently be called, may be a very serious matter when it occurs—witness the rapid death from anaphylactic shock of animals injected with foreign protein appropriately dosed and spaced. It is well, therefore, to recall the statement in the Memorandum that the danger of anaphylactic shock is negligible when the prophylactic dose is contained in such a small quantity as 3 c.c. of horse serum, whatever the interval after the preceding injections. Highly concentrated serum in doses sufficient to maintain protection may be repeated at weekly intervals as long as is considered advisable without any fear of the occurrence of anaphylaxis.

So much for prophylaxis. The case is somewhat different in regard to the massive doses demanded in curative treatment after symptoms of toxæmia have already shown themselves. The large doses of horse protein which necessarily accompany the requisite number of antitoxic units may be a source of inconvenience or danger. The paper by Captain S. WYARD, R.A.M.C., which we print this week, sets out clearly and simply how these inconveniences can be entirely avoided. A small rectal injection of antigen within 12 hours renders the individual refractory to a subcutaneous dose of any size, or if this amount of delay is held inadvisable the same result can be obtained by a succession of subcutaneous doses, beginning with a very small dose and rapidly rising to a large and efficient one. Observance of these precautions should be sufficient to remove all risks of anaphylaxis, and the fear of its occurrence can no longer justify the failure to employ protective serum in every case where it can possibly be of service.

### Annotations.

"Ne quid nimis."

### NEW FOOD ORDERS.

THE new Orders issued by the Food Controller last week will disturb still further part of the customary dietary of most of us. An increased economy of wheat material is suggested, and instead of 76 per cent. now extracted from the grain, a further 5 per cent., making a total of 81 per cent., is insisted upon. The Order is probably based upon the fact that the public have found the new bread acceptable, and, that being so, a further extraction of 5 per cent. from the total grain will produce an equally acceptable loaf and effect a further important economy. For the first time, however, an option is given to the miller to mix with the wheat flour derived from barley, maize, rice, or oats to the extent of 10 per cent. This means that the miller need not mill his wheat further than the original allowance of 76 per cent. if, as an alternative, he chooses to add a proportion of other flours. We made a similar suggestion to this in a leading article in THE LANCET of Jan. 30th, 1915, when we said it would be possible to add to rich gluten flours a proportion of starch, as, for example, maize flour (cornflour), without materially reducing the nitrogen value when compared with a low-grade wheat flour. The energy value of such a loaf would be quite high, while its nourishing properties would be little impaired. Maize flour or rice, however, would carry in little more food material than starch, while barley and oats would add proteins and fat, and from a dietetic point of view the loaf containing an addition of barley and oats would, likely enough, have a superior value to the loaf made with a similar proportion of maize or rice. To those who hold that bread is primarily eaten not as a source of protein, but as an easily digestible, attractive form of starch, it matters little which flour is employed. Obviously, however, the wheat substitutes can be used for no good purpose unless they are cheaper than wheat-flour itself. Apart from this question, there must be considered also the physical qualities of the loaf;

<sup>1</sup> THE LANCET, Nov. 18th, 1916, p. 873.

texture, for one thing, is an important property. It is not all cereals which will make a light, spongy bread, and wheaten flour is easily first in producing a loaf of uniform porosity which is an essential characteristic of a bread that is to be easily masticated and digestible. The lumpy, sodden loaf is unattractive besides being indigestible, and its food value may be largely discounted owing to its causing gastric difficulty. The new Order, we take it, exempts the baker from the old requirements of the Bread Act if he chooses to use other flours than wheat. According to this Act, a loaf of bread containing any other flour than wheat must be marked with a large capital letter M, and there is liability to a heavy penalty if this is neglected. The old controversy as to whether sugar is an essential in our dietary has been revived, and more than one well-known physiological authority has stated that sugar is not a natural food, inasmuch as the human economy is constructed to convert carbohydrate—e.g., starch, which they claim to be a natural foodstuff—into sugar. It is quite certain that if sugar were tasteless or not sweet it would not be so popular as it is, and so from this point of view it must rank as a condiment as well as a food. It is interesting to recall that sugar was scarcely a commercial commodity much more than a century ago, and in the time before that our ancestors got on very well without it, while, as a matter of fact, a big section of the community consumes nowadays very little or none of it. The history of starches in the dietary, however, goes back to the beginning of things, and there was always a supply of starches long before sugar was cultivated or thought of in its present form. Custom and cheapness have brought sugar into wide use, and we are glad to note that its employment in many extraneous and totally unnecessary ways is prohibited.

#### THE MORITZ-WEISS REACTION IN SURGICAL PRACTICE.

THE permanganate test was believed by its discoverer to have a special diagnostic and prognostic value in tuberculosis. Moritz-Weiss in 1911 affirmed that when the reaction was positive in the urine of persons suffering from tuberculosis the patient had little chance of recovery owing to the extension of the tuberculous process or to his small resistance to Koch's bacillus. It was further claimed that this test was superior to the diazo-reaction for several reasons: greater simplicity of technique, greater sensitiveness, and the lesser influence on it of substances given medicinally. The original technique is as follows. The urine for examination, which must be perfectly clear and not have undergone ammoniacal fermentation, is diluted with twice its volume of water. To a test-tube of this mixture three drops of a 1 per cent. aqueous solution of permanganate of potash are added and shaken. If the reaction is negative the liquid does not change colour or takes a faint violet brown tinge; if positive it becomes golden yellow. The reaction was said not to occur in normal urine, and was not produced by the ingestion of certain drugs, such as creosote and opium, which influence the diazo-reaction. Dr. Carlo Belgrano published in the Surgical Section of *Il Policlinico*, Sept. 15th, 1916, the results obtained by the systematic testing of the urine in 369 surgical patients, repeating

test at intervals so as to ascertain the behaviour of the reaction at various phases of the course of the disease. The cases included surgical tuberculosis, acute local and general inflammatory processes, gangrene, malignant tumours, and varicose ulcers. The conclusions arrived at from these experiments were to the effect that the Moritz-Weiss reaction was not specific for tuberculous disease, although it was more frequently present in diseases of this kind than in others, and that it occurred for the most part in the urine of individuals suffering from serious diseases which produce rapid cell disintegration—that is, in cases where high temperature was present associated with profuse suppuration. The reaction, according to Dr. Belgrano's observations, seemed devoid of any prognostic value, for though it almost always coincided with the phase of the greatest severity of the disease it did not necessarily indicate an unfavourable prognosis. Furthermore, the reaction disappeared and reappeared during the course of the disease, its disappearance coinciding, as a rule, with a period of improvement in the patient.

#### DOUBLE EMPYEMA SUCCESSFULLY OPERATED UPON.

CASES of operation for double empyema are rare. In the *Boston Medical and Surgical Journal* recently Dr. F. B. Lund and Dr. H. Morrison have reported the following case. A girl, aged 16, was attacked on March 30th, 1915, with epigastric pain, vomiting, headache, and slight cough. The temperature was 102° F., pulse 120, and respirations 30. There were signs of beginning consolidation at the base of the left lung. From the commencement the patient looked very ill. On April 1st her leucocyte count was only 5000. On April 2nd the right lower lobe was affected, and by the end of the ninth day the middle and lower lobes of the right lung and the lower lobe of the left were solid. The temperature ranged from 100°–101° mornings to 103°–104° evenings. There was slight cyanosis, with considerable dyspnoea, and the sputum was muco-purulent and very tenacious. The crisis failed to appear during the next six days. The patient was prostrated; she was running a septic temperature and was beginning to perspire freely. At both bases and the axillæ there developed "flatness" below the level of the angle of the scapula with distant bronchial breathing and bronchophony. Above this zone were fine crepitant râles. On April 14th she was sent to the Boston City Hospital, with the provisional diagnosis of double empyema. An X ray examination showed increased density in the left lower lobe, suggesting consolidation rather than fluid. Dr. Lund performed paracentesis in two places on each side of the chest with no result. On April 18th she began to cough up a great deal of foul pus, without relief. On April 21st the left chest was again tapped. This time a few drops of thick pus were obtained in the ninth interspace in the posterior axillary line. Resection of the ninth rib was done with the evacuation of several ounces of thick foul pus, similar to that which the patient was expectorating. Drainage was established through a rubber tube inserted obliquely, with the skin sutured over the end to act as a valve. On the following morning the patient's condition had not improved, and the right pleural cavity was explored a second time. A needle inserted through the tenth interspace near the spine, and directed upward, obtained a few drops of pus. The tenth rib was

resected near the vertebra, and a few ounces of foul pus were found between the right lung and the spine. Drainage was established through a rubber tube. The patient began to improve at once. There was profuse drainage through both tubes. The cough and expectoration gradually subsided. By the end of May both wounds were granulating, and there was very little discharge through the small sinuses. On May 29th an X ray examination showed no evidences of fluid in the chest; there was some haziness throughout both lungs, but they were well expanded. Complete recovery followed. Evidently the double empyema followed pneumonia. When the patient began to expectorate fetid pus there must have been a perforation through the lung.

#### TRICHOMONAS DYSENTERY AT AREQUIPA.

FOR a long time cases of dysentery, some of them fatal, have been occurring at Arequipa, a town of about 35,000 inhabitants situated at the foot of the Peruvian Andes. Many of these cases were recognised to be of the amebic form, but others occurred in less amount of the balantidial kind, and some of mixed forms: the prevailing type was that due to infection by *Trichomonas intestinalis*, a small protozoal parasite, which was found in abundance in the stools of the patients. Papers on this subject were published not long ago in the *Bulletin de la Société de Pathologie Exotique* (vol. vi., No. 2, and vol. vii., Nos. 8 and 9) by Dr. Edmundo Escomel, of Arequipa, who, in studying the protozoal organisms present in the potable water of that town, discovered *T. intestinalis* in the public service in adult forms and in the cystic stage. In particular, he found the organism in considerable amount in the distributing reservoir, which was inadequately protected against contamination from various sources. One of its feeders, for instance, was a small stream in which women from the town were accustomed to wash their body linen and other articles. Steps were at once taken by Dr. Escomel, who held the appointment of medical examiner of the public water-supply, to protect the water service from pollution, and particularly to guard the distributing reservoir from contamination. Since this was done trichomonas dysentery has entirely disappeared from Arequipa. It is of interest to mention that while this form of dysentery was prevalent Dr. Escomel found that no benefit followed the administration of ipecacuanha, but that considerable improvement resulted from giving the essence of terebinthine. Later, as a result of experiments *in vitro*, he found that the trichomonas organisms died as soon as they came in contact with a solution of iodine (1 in 1000). He, therefore, with success treated his later patients by enemas containing a dilute solution of iodine, and he claims for this method that, though simple, it is most efficacious in the majority of instances.

#### TWO SOUTH AFRICAN MEDICAL MEN.

A CORRESPONDENT in South Africa has called our attention to the many points in common presented by the widely differing careers of two medical men whose deaths have just occurred. Dr. Josiah Wright Matthews, an intimate friend of Cecil Rhodes, lost and made in speculation three fortunes, and died at Greytown, Natal, on Dec. 5th last, at the age of 76. Qualifying in 1864 as L.S.A. Lond., L.F.P.S. Glasg., he

graduated later as M.D., C.M., at the University of Aberdeen in 1871. His public and professional life was spent in South Africa, where he commenced practice as district surgeon at Verulam. Subsequently he became one of the pioneers of the diamond fields at Kimberley, where he did much valuable work in hospital reform. On the annexation of Griqualand to the Cape he was elected Member of Parliament for Kimberley. In later years he was a prominent public man at Barberton. As a traveller he had many interesting reminiscences to record, and these were embodied in a book which he published some years ago under the Zulu title of "Incwadi Yama." Five days later Dr. William Russell, who for many years was resident surgeon at the Kimberley Hospital, died from pneumonia, after a protracted illness, at the comparatively early age of 48 years. Dr. Russell also qualified with honours as M.D. at Aberdeen University in 1896, after having obtained his M.B., C.M. in 1890 and his D.P.H. (Eng. Conj.). He was resident surgeon for several years at Toxteth Infirmary, Liverpool, and later was superintendent of hospitals at Maidstone during the typhoid epidemic there in 1897. He was the author of a clinical record of over 500 cases of typhus fever, and also wrote a thesis on accidental rash in typhus and typhoid fevers simulating the rash of scarlet fever. Going out to South Africa in 1898, 30 years later than Dr. Matthews, Dr. Russell served for a while in temporary appointments, and later became senior house surgeon of the Kimberley Hospital, and was very popular among all classes of the people of the diamond fields. He held this office with great credit during the time when the town was besieged by the Boers, and relinquished the post three years ago in order to enter upon private practice. His tireless devotion to duty during the siege was acknowledged in an autograph letter sent to him by direction of Queen Victoria and by another from Lord Roberts.

#### A WAR-TIME PATHOLOGICAL MUSEUM.

THE collection of specimens of pathological interest from military hospitals at the Royal College of Surgeons has now reached a stage at which a selection can usefully be made for immediate study. Major T. R. Elliott, who was placed in charge of the collection and transmission of the specimens from the laboratories of the base hospitals in France, has been successful in obtaining a total, so far, of over 1100, and these have been stored and indexed. Professor S. G. Shattock, with the help of the pathological assistant to the College, is going through the specimens with a view of making a representative selection, for which purpose Mr. Raymond Johnson has placed his experience at their disposal.

THE King has appointed Sir William Whitla to be one of His Majesty's honorary physicians in Ireland in the room of the late Dr. James Little.

CENTENARIANS.—Mrs. Sarah Brooks, an Essex centenarian, died recently in her 105th year, and Mr. John Froggett has died at Offerton, Cheshire, aged 102 years and six months. He had 80 descendants, and 14 of his grandsons are serving in the Army.—Miss Bailey, of Esher, has received the congratulations of the King and the Duchess of Albany on the attainment of the 100th anniversary of her birthday.

THE LANCET, VOL. II., 1916 :  
THE INDEX.

THE Index and Title-page to the volume of THE LANCET completed with the issue of Dec. 30th will be ready on Jan. 22nd. Owing to the continued shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a post-card to the Manager, THE LANCET Office, 423, Strand, London, W.C., when a copy of the Index and Title-page will be supplied free of charge.

THE CONTROL OF VENEREAL DISEASES.

*The Midwife's Share in the Informal Notification of Syphilis.*

A PASSAGE in the Liverpool scheme which we have already briefly summarised calls attention to the systematic examination by the city bacteriologist of stillborn infants. Through the co-operation of the midwives Professor J. M. Beattie is now enabled to examine a large proportion of the infants born dead before term and, as Dr. E. W. Hope states in the report, has found that in a great majority of these syphilis was the cause of the stillbirth. The services of the midwife are then further utilised to induce the mother to attend at the bacteriological department for the examination of her blood by the Wassermann test. If this is found to be positive, a little further persuasion on the part of the midwife, as the recognised friend and adviser of the family, has almost without exception resulted in the treatment of one or both parents. We learn that up to the present time out of a total approaching 100 only a single individual has refused treatment for himself and his wife. No compulsion, of course, is available. It is easy to see how the trouble which the Public Health Department of Liverpool has taken to get and keep in sympathetic relations with the midwife has resulted in a helpful addition to the administrative machinery of its venereal scheme. The informal and friendly action of the midwife amounts to an effective system of voluntary notification without any of the attendant drawbacks of the latter.

*The Suppression of Unqualified Practice.*

At the quarterly meeting of the Council of the Royal College of Surgeons of England on Jan. 11th a resolution was adopted stating that it is urgently necessary, for the protection of the public, to prohibit under penalty the treatment of venereal diseases and the advertisement of such remedies by unqualified persons. The Council considered that the recommendations of the Select Committee of the House of Commons on Patent Medicines should forthwith be adopted and embodied in the proposed legislation.

A recent meeting of the Council of the Association of Municipal Corporations dealt with the same subject. A resolution, moved by the Town Clerk of Barrow-in-Furness—

That in the opinion of this association administrative measures for the diagnosis and treatment of venereal diseases will only attain their maximum effectiveness in protecting the public health when the treatment of such diseases by unqualified persons is prevented by law—was carried, and copies were forwarded to the Prime Minister and to the President of the Local Government Board, asking for the introduction of the necessary legislation as early as practicable.

*Galyl as an Approved Salvarsan Substitute.*

We have received the following letter from the Anglo-French Drug Company (Gamage Buildings, Holborn, London, E.C.) :—

We are receiving queries from medical men and hospital authorities regarding the omission of galyl from the list of approved remedies on the Local Government Board circular. They seem to be under the impression that the omission is due to some therapeutical objection—whereas it is really owing to the miscarriage of some correspondence on the

matter with the secretary of the Local Government Board. We hope to see galyl on the approval list in the very near future.

*Death Accelerated by a Salvarsan Substitute.*

An inquiry was held in the Southwark coroner's court on Jan. 6th concerning a man, aged 33, who died in Guy's Hospital after the administration of arsenobenzol. An intravenous dose of 0.4 grm. arsenobenzol was given and the patient died suddenly two hours after the injection. Dr. B. H. Spilsbury, who made a post-mortem examination and found a large tumour in the front part of the brain with extensive softening of the brain, stated his opinion that death was due to coma from disease of the brain, accelerated by the administration of arsenobenzol. A verdict of "Death by misadventure" was given.

*Campaign of Publicity.*

Two lectures of the series on public health problems, arranged by the Royal Institute of Public Health, will be devoted to the prevention and arrest of venereal disease. Dr. Mary Scharlieb deals with the subject in women on Jan. 24th and Dr. C. J. Macalister in men on Jan. 31st. On the former occasion Dr. A. Newsholme will take the chair and on the latter Lord Sydenham. Discussion is provided for after the lecture. Time and place are 4 P.M. at 37, Russell-square, London, W.C.

A course of four lectures for men has been arranged by the Liverpool Medical Institution as a branch of the National Council. The first was delivered last week by Dr. E. W. Hope on the Royal Commission's Report. Dr. R. W. MacKenna will lecture on Venereal Diseases (Jan. 19th), Professor J. M. Beattie on Social Prevention (Jan. 26th), and Dr. C. J. Macalister will preside at a conference (Feb. 2nd). Time and place are 8 P.M. at the Picton Lecture Hall, William Brown-street, Liverpool.

Sir Malcolm Morris has attempted a simple exposition of venereal diseases with special reference to their bearing upon public health in a book of 150 pages entitled "The Nation's Health," just published by Messrs. Cassell and Co. (price 3s. 6d. net). It is intended for the use of members of local authorities and of hospital boards, and for headmasters and headmistresses. The early chapters describe in non-technical language the manifestations of syphilis and gonorrhoea, their prevalence, the means of enlightenment and of providing facilities for their treatment. The questions of notification, regulation, and other administrative measures are then discussed. The book will serve a useful purpose, but the subject-matter of the book should not have been cloaked in an obscure title, the sub-title, "The Stamping Out of Venereal Diseases" not appearing on the cover at all. Undue prominence is given to a story indicating the infectiousness of syphilitic sores of the lip; the story is taken from the pages of an American journal.

*Council and Other Schemes.*

A private conference of doctors, clergy, and of citizens representative of various health, nursing, and public morals societies, was held in the City Hall, Belfast, last Thursday, to discuss the establishment of a local branch of the National Council for Combating Venereal Diseases.—Mr. F. S. Kidd lectured at the Trowbridge Council Chamber to the medical practitioners and officers of the R.A.M.C. in the county of Wilts on Wednesday last, by invitation of Dr. J. Tubb-Thomas, county medical officer. The address was on Modern Methods of Treatment and Diagnosis of Diseases of the Male Urethra.—At Exeter the local members of the medical profession have nominated Mr. A. C. Roper and Dr. Mabel E. Gates to advise the sanitary committee.—The committee of the Devon County Council, who are making arrangements with the local authorities for the treatment of venereal disease, has recommended that the following members of the medical profession should attend the meetings of the committee and advise: Mr. Russell Coombe, Mr. S. Noy Scott, Mr. Ellis Pearson, and Dr. G. F. Welsford.

**LONDON HOSPITAL MEDICAL COLLEGE.**—A course of three lectures on the Modern Treatment of Diabetes Mellitus will be given in the clinical theatre of the hospital by Dr. O. F. Leyton, physician to the hospital, on Wednesdays, Feb. 7th, 14th, and 21st, at 5.15 P.M. Members of the medical profession will be admitted on presentation of card.

## Public Health.

### ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

*City of Liverpool.*—Dr. E. W. Hope's annual report for the year 1915, in common with most current annual reports of medical officers of health, is considerably reduced in size, but contains an excellent account of the activities of the public health department during the year under review. The population of Liverpool at the middle of the year 1915 was estimated at 772,595, an increase over the previous year of 4603. There were 21,586 births within the city, giving a birth-rate of 27·9 per 1000 of the population, the average of the previous five years (1910-14) being 30·0. There has thus been a considerable decline compared with preceding years, but the birth-rate of Liverpool is still well above the average of the great towns, which is 22·8 per 1000, as well as of England and Wales taken as a whole, which gives a rate of 21·8 per 1000. The total death-rate was 18·7 per 1000, as against 19·5 during the previous year. Zymotic diseases were the cause of 1959 deaths during the year, giving a rate of 2·5 per 1000, as compared with 2·6, which was the average rate for the preceding five years. As Liverpool, on account of the large number of ships continually arriving in the port, is peculiarly liable to the introduction of diseases from abroad, it is satisfactory to learn that no case of plague occurred in the city during the year. As a precautionary measure, the systematic catching and examination of rats has been further extended and all the usual preventive methods were employed at the docks and in warehouses, &c. A small localised outbreak of typhus fever occurred in the latter half of the year, the infection probably having been introduced from Ireland by means of lice-infected material. There were 37 cases and 6 deaths. The number of enteric fever cases was 136, 21 of which had a fatal termination. Only 3049 cases of measles were reported, as compared with 6426 in the previous year. These figures do not, however, represent the total number of measles cases occurring in the city, but have reference, for the most part, to those coming to the notice of the school authorities. The deaths from this disease numbered 256, as against 517 in 1914. The deaths from whooping-cough numbered 259, showing a slight increase over the preceding year, when there were 248. There were 2866 deaths among infants under one year, giving an infantile mortality rate of 133 per 1000 births. Much is being done to lessen the infantile mortality in Liverpool. As many as 95 per cent. of all births notified under the Notification of Births Act, 1907, have been visited by the health visitors during the year.

*City of Cork.*—There are some interesting items of information in Mr. Denis D. Donovan's annual report for the year 1915. The reduction in the number of cases of typhus fever in the city is well illustrated by the following figures. During the ten years 1879-88 there were 4836 cases; during the next decade 1889-98 there were 547 cases; and during the decade 1899-1908 there were 122 cases, whilst 18 cases were notified in 1909, 8 in 1910, 10 in 1911, 1 in 1912, 5 in 1913, 1 in 1914, and none in 1915. In this connexion Mr. Donovan states:—

In my annual report for 1886 I pointed out that the opening of new areas in the congested districts, and the building of cottages for the working class population would have a decided effect in the reduction of typhus fever. This statement is now more than borne out by facts. There has also been a considerable reduction in the number of enteric fever cases. In the ten years 1879-88, 793 cases of this disease occurred; in the following decade, 1889-98 there were 879 cases; while during the ten years 1899-1908 there were only 512 cases. The number of cases notified in 1909 was 74; in 1910, 54; in 1911, 32; in 1912, 26; in 1913, 29; in 1914, 50; and in 1915, 32. In commenting on the prevalence of enteric fever the medical officer of health informs us that some years ago a number of shallow wells were in existence in different parts of the city. As the water in these wells was found to be polluted, they were closed. Up to the year 1889 the main sewers were not ventilated; since this was done the disease has materially diminished. An effort is also being made to remedy the faulty old house drains and bad connexions that are to be met with all over the city. Mr. Donovan expresses the view that if the periodical flooding that occurs from time

to time in the central flat portion of the city could be dealt with and the subsoil properly drained there would be less typhoid fever than at present. The birth-rate of Cork for the year under review is 23·18 per 1000 of the population and the infant mortality-rate 132 per 1000 births. By the passing of the Notification of Births (Extension) Act, 1915, the Notification of Births Act, 1907, came into force in the city on Sept. 1st. Under the provisions of the Infectious Disease (Notification) Act, 1889, epidemic diarrhoea has been made compulsorily notifiable. A "lady sanitary sub-officer," who is qualified to give the necessary advice and instruction to mothers regarding their own health and the care and proper feeding and clothing of their infants, has for some time been on the staff of the health department. It is hoped that, through her exertions, the number of deaths of infants will be somewhat reduced. The statement appears in this annual report that the city of Cork is in the unenviable position of having the highest consumptive death-rate of any town in Great Britain and Ireland. There were 211 deaths from this disease in 1915, or about one-eighth of the total number of deaths registered during the year. The death-rate from the malady was 2·88 per 1000. A system of voluntary notification, to which we have recently called attention, was introduced in 1907, but apparently it has proved to be of little value, and Mr. Donovan urges his council to adopt obligatory notification.

### ANNUAL REPORTS FROM INDIA.

*The Health of Bombay in 1915.*—The population of Bombay in 1911 amounted to 979,445. The total death-rate in 1915 was 24·17 per 1000, comparing most favourably with the ratio of 35 per 1000 for the preceding quinquennium 1910-1914; the ratio is, indeed, lower than in any year since 1874, when it was 24·04 per 1000. The male death-rate was 20·33, and that for females 31·43 per 1000. It is stated by Dr. J. A. Turner, the health officer to the municipality, that "this inequality of rates of mortality among males and females is largely to be accounted for by the preponderance of males, who form nearly two-thirds of the population." About two-thirds of the inhabitants are Hindus of various castes, with an average mortality ratio of 22·77; the Mussulmans have a ratio of 30·89, while for Parsees the ratio is only 18·82 and for Europeans 13·62. The infantile mortality, 329·2 per 1000 births, is much lower than in the previous year (385·1); among Hindus the ratio was 350 and among Parsees 153 per 1000. Much has been done by means of lady health visitors, midwives, a maternity home, and the provision of milk, bed and blanket for such mothers as cannot go to the home, but all this only touches the fringe of the problem, since about 76 per cent. of the population live in one-room tenements. In Bombay, as in Calcutta, much has been done to ameliorate the conditions affecting child-birth, ten trained midwives having been appointed under Lady Willingdon's scheme to act as health visitors and induce prospective mothers to enter the municipal maternity home. A similar home at Parel and one at Colaba will before long be established. As regards epidemic diseases, the incidence was lower in 1915 than in the previous year, and in the decennium, in every case except small-pox, for which the death-rate was 0·36, compared with 0·25 in 1914 and 0·72 in the decennium (1905-1914). The most notable feature during the year was the reduction of plague to the smallest proportions on record; there were 599 deaths, giving a death-rate of 0·61 per 1000. In 1914 the ratio was 3·00, and for the decennium (1905-1914) it averaged 5·93 per 1000. The usual preventive measures—inoculation, rat destruction, evacuation and disinfection—were carried out. Small-pox prevailed to some extent, there having been 775 attacks compared with 252 in the previous year. Tuberculosis continues to decline rapidly; in 1900 the mortality ratio was 10·53 per 1000; in 1905 it was 4·10, and in 1915 only 1·74 per 1000. Lastly, the ratio for fevers (1·74 deaths per 1000) was less than in any previous year or period for which statistics are available; of the total deaths from this cause (2091), all were from malaria except 109, which were due to enteric fever. Much work is being done in regard to the control of tuberculosis; the King George V. Antituberculosis League was started, an executive committee formed, a dispensary and hospital accommodation for 25 patients were provided. Various measures have also been undertaken for improving the general sanitary condition of a particular area found to have a high tuberculous death-rate. Enteric fever has shown an apparent increase during recent

years, but it is probable that this is due to increased care in diagnosis. Dr. Turner's report on the health of Bombay is extremely interesting, and is illustrated by numerous tables and a map.

*The Health of Calcutta in 1915.*—The report of Dr. H. M. Crake for 1915 shows the enormous difficulties that have to be contended with in maintaining anything approaching satisfactory sanitation under the existing conditions of climate and overcrowding. Dr. Crake has calculated the ratios throughout on a population of 896,097, as ascertained by census in 1911, rather than on any hypothetically increased number of inhabitants present in 1915, and shows that any estimate of the latter must be of doubtful accuracy. The total death-rate was 28·5 per 1000, practically the same as the quinquennial average (28·6). As always, the mortality among females (37·8) largely exceeded that among males (24·1), due to the strict *purdah* system under most insanitary conditions. The highest female death-rate was 51 per 1000, in Kidderpore Ward, where the male rate was also highest, 48·1 per 1000. In Burra Bazar the female death-rate was 32·6, and the male rate only 15 per 1000; many other districts present a similar excessive female mortality. Approximately half the inhabitants of Calcutta are Hindus, with a death-rate of 29·2; that for Mahomedans being 28·0 and for Christians 25·9 per 1000. The infantile mortality (287·6) was higher than in any of the four years preceding, due especially to debility at birth, tetanus, and bronchitis. Tetanus is, of course, due to dirty midwifery, for we learn that "there has never been a single case amongst the hundreds of babies brought into the world by the corporation midwives." It is hoped that before long "baby clinics" will be established. A severe epidemic of small-pox, lasting seven months, resulted in 2560 deaths; as nearly half the deaths occurred among infants and young children under 5 years it is evident that large numbers escaped vaccination. Among the satisfactory signs of progress the extension and acceptance of vaccination is most encouraging. The total number vaccinated, 100,720, constitutes a record. The majority (77,518) were revaccinations, being about ten times the average of a non-epidemic year. The percentage of success was 39·4. Plague as an epidemic has practically disappeared, there having been only 191 deaths. There was, however, heavy rat mortality, mostly in the first three months of the year. Tuberculosis caused 1920 deaths (2·1 per 1000), the lowest record during five years. The female mortality (3·18) was double that of the male (1·6). Cholera caused 1612 deaths (1·8 per 1000), the smallest number recorded during the last 16 years. In Kidderpore Ward the ratio was 3·7 per 1000, infection being undoubtedly conveyed through contaminated water at the bathing-places. Malaria caused 1258 deaths (1·4 per 1000), and was more fatal than usual in certain wards lying east of Upper Circular-road. As the sewerage system becomes extended and the area more thoroughly drained there will certainly be a decided improvement. Anti-mosquito measures were carried out most energetically in certain wards principally affected by malaria, tanks breeding anopheles being treated three times a month. The commonest forms found in the suburban areas were *Anopheles rossii* (50 per cent.), *nigerinus*, and *barbirostris*. In view of the opening of the Panama Canal a plan of operations has been worked out for dealing with the stegomyia problem. The most urgent matter at present is stated to be the control of stegomyia in the Fort area, where there appears to be an absence of an adequate general sanitary organisation. Observations were made on the effects of storage of the Hugli river water, in comparison with sand filtration; in the settling tanks lactose-fermenting bacteria were generally found in 5 c.c., but rarely in 1 c.c., while in the filtered water they were generally absent in 10 c.c. The report is accompanied by numerous diagrams, tables, and a map.

#### URBAN VITAL STATISTICS.

(Week ended Jan. 6th, 1917).

*English and Welsh Towns.*—In the 96 English and Welsh towns, having an aggregate population estimated at nearly 18,000,000 persons, the annual rate of mortality during the week was equal to 18·9 per 1000 of the population, against 23·7 and 21·9 per 1000 in the two preceding weeks. Among the several towns the death-rate ranged from 8·9 in Rotherham, 10·6 in Cambridge, and 11·9 in Gloucester, to 27·7 in Oxford, 29·6 in Bath, and 35·4 in Bournemouth. The annual rate in London, with a population of more than 4,000,000, was equal to 19·6, or 4·1 per 1000 less than that recorded in the previous week. In the 96 towns, the principal epidemic diseases caused 207 deaths,

which corresponded to a rate of 0·6 per 1000, and included 64 from infantile diarrhoea, 61 from measles, 50 from diphtheria, 17 from whooping-cough, 8 from scarlet fever, and 7 from enteric fever. The deaths from each of these diseases were below the average in the four preceding weeks. The deaths from diphtheria included 11 in London, 5 in Birmingham, and 3 in Derby. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospitals had further declined at the end of the week to 869; and the cases of diphtheria had also declined to 1431. Of the 6270 deaths from all causes in the 96 towns, 216 resulted from violence. The causes of 68 of the total deaths were uncertified, of which 15 were registered in Birmingham, 11 in Liverpool, and 4 in St. Helens.

*Scotch Towns.*—The deaths registered in Glasgow numbered 397, and were equal to an annual rate of 18·6, against 19·6 per 1000 in London, and included 7 from infantile diarrhoea, 4 from whooping-cough, 2 from diphtheria, and one each from measles and scarlet fever. Of the 397 deaths, 77 were of infants under 1 year and 92 of persons aged 65 years and upwards. The 117 deaths from all causes in Edinburgh corresponded to an annual rate of 18·4 per 1000, and included 7 of infants under one year and 44 of persons aged 65 years and upwards. Four deaths were referred to diphtheria, and one each to whooping cough and infantile diarrhoea.

*Irish Towns.*—The 202 deaths registered in Dublin during the week were equal to an annual rate of 26·4 per 1000, and included 4 from infantile diarrhoea, 2 from measles, and 1 from enteric fever. The causes of 9 deaths were uncertified. The 145 deaths in Belfast corresponded to an annual rate of 19·2, against 21·3 per 1000 in the previous week. These deaths included 2 from infantile diarrhoea and 1 each from measles and diphtheria. The causes of 5 of the total deaths were uncertified.

(Week ended Jan. 13th, 1917.)

*English and Welsh Towns.*—In the 96 English and Welsh towns having an aggregate population estimated at nearly 18,000,000 persons, the annual rate of mortality during the week was equal to 16·8 per 1000 of the population, against rates declining from 23·7 to 18·9 per 1000 in the three preceding weeks. Among the several towns the death-rate ranged from 6·6 in West Hartlepool, 8·0 in Grimsby, and 10·0 in Easbourne, to 22·6 in St. Helens, 24·8 in Bury, and 27·0 in Hastings. The annual rate in London, with a population of more than 4,000,000, was equal to 17·6, or 2·0 per 1000 below that recorded in the previous week. In the 96 towns the principal epidemic diseases caused 210 deaths, corresponding to a rate of 0·6 per 1000, and included 67 from infantile diarrhoea, 57 from measles, 45 from diphtheria, 25 from whooping-cough, 10 from enteric fever, and 6 from scarlet fever. The deaths from enteric fever and whooping-cough exceeded, while those from the remaining diseases were below, the average in the three preceding weeks. Measles caused a death-rate of 3·7 in Wimbledon; of the 46 deaths referred to diphtheria, 9 occurred in London, and 4 each in Birmingham and Liverpool. The number of scarlet fever and diphtheria patients in the Metropolitan Asylums Hospitals and the London Fever Hospitals had further declined to 829 and 1395 respectively by the end of the week. Of the 5594 deaths from all causes in the 96 towns, 193 resulted from violence. The causes of 46 of the total deaths were uncertified, and included 10 in Liverpool, 8 in Birmingham, and 5 in Gateshead.

*Scotch Towns.*—The 388 deaths recorded in Glasgow corresponded to an annual rate of 18·1, against 17·6 per 1000 in London, and included 9 from whooping-cough, 5 from infantile diarrhoea, 3 from diphtheria, 2 from measles, and 1 from enteric fever. Of the 388 deaths, 59 were of infants under 1 year and 110 of persons aged 65 years and upwards. In Edinburgh the 114 deaths were equal to a rate of 17·9, or 0·5 per 1000 below that in the previous week, and included 3 from diphtheria and 1 from whooping-cough.

*Irish Towns.*—The 161 deaths registered in Dublin were equal to an annual rate of 21·0 per 1000, and included 3 from measles and 1 from infantile diarrhoea. The causes of 12 deaths were uncertified. The 155 deaths in Belfast corresponded to a rate of 20·6, or 1·4 per 1000 above that in the previous week, and included 4 from infantile diarrhoea and 1 each from whooping-cough and diphtheria.

#### VITAL STATISTICS OF LONDON DURING DECEMBER, 1916.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 3·9 per 1000 of the population, estimated at 4,310,030 persons in the middle of the year; in the three preceding months the rates were 4·9, 5·4, and 5·0 per 1000. The lowest rates last month were recorded in the City of Westminster, Hampstead, Stoke Newington, the City of London, and Wandsworth; and the highest rates in Holborn, Bethnal Green, Stepney, Deptford, and Greenwich. The prevalence of scarlet fever showed a marked decline from that recorded in the preceding month; this disease was proportionally most prevalent last month in Paddington, Kensington, Fulham, Bethnal Green, Bermondsey, and Lewisham. There were 913 scarlet fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 1117 and 1066 at the end of the two preceding months; the weekly admissions averaged 95, against 160 and 131 in the two preceding months. Diphtheria also was much less prevalent than it had been in other recent months; the greatest proportional prevalence of this disease was recorded in Holborn, Bethnal Green, Stepney, Southwark, Deptford, and Greenwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1479 and 1543 at the end of the two preceding months, had declined again to 1479 at the end of last month; the weekly admissions averaged 143, against 209 and 187 in the two preceding months. The prevalence of enteric fever was considerably less than in either of the two preceding months; of the 23 cases notified during the month, 4 belonged to Islington, 4 to Wandsworth, 3 to Camberwell, and 2 to Paddington. The Metropolitan Asylums Hospitals contained 37 enteric fever patients at the end of last month, against 39 and 42 at the end of the two preceding months; the weekly admissions averaged 5, against 7 in each of the three preceding months. Kyselipas was proportionally most prevalent last month in Paddington, Holborn, Bethnal Green, Poplar, Deptford, and Greenwich. The 29 cases of puerperal fever included 4 in Camberwell, 3 in Fulham, 3 in

Wandsworth, and 2 each in Kensington, Islington, Stepney, Poplar, Bermondsey, and Woolwich. Of the 24 cases of cerebro-spinal meningitis, 4 belonged to Islington, 4 to Finsbury, 3 to Lambeth, 2 to Stepney, and 2 to Woolwich; while the 5 cases of poliomyelitis belonged respectively to Hammersmith, Stepney, Bermondsey, Lambeth, and Lewisham.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several metropolitan boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ended Dec. 30th the deaths of 7475 London residents were registered, equal to an annual rate of 22.6 per 1000 of the population; in the three preceding months the rates were 12.0, 12.0, and 14.5 per 1000 respectively. The death-rates last month ranged from 14.7 in the City of London, 18.3 in Lewisham, 18.8 in Hamps ead, 19.0 in Wandsworth, 19.4 in Hackney, and 19.6 in Stepney, to 25.9 in Southwark, 26.4 in Kensington, 26.7 in Shoreditch, 26.9 in St. Marylebone, 28.8 in Finsbury, and 29.0 in Chel-sea. The 7475 deaths from all causes included 271 which were referred to the principal infectious diseases; of these, 99 resulted from measles, 5 from scarlet fever, 49 from diphtheria, 15 from whooping-cough, 3 from enteric fever, and 100 from diarrhoea and enteritis among children under two years of age. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates.

in Kensington, Hampstead, Holborn, and Wandsworth, and the highest rates in Chelsea, Shoreditch, Bethnal Green, Poplar, Bermondsey, Greenwich, and Woolwich. The 99 fatal cases of measles were 16 fewer than the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal last month in Bethnal Green, Poplar, Southwark, Bermondsey, Greenwich, and Woolwich. The 5 deaths from scarlet fever were 14 below the corrected average number, and included one each in St. Marylebone, Stoke Newington, Southwark, Lambeth, and Camberwell. The 49 fatal cases of diphtheria showed a decline of 6 from the corrected average number; the greatest proportional mortality from this disease was recorded last month in Chelsea, Bethnal Green, Stepney, and Camberwell. The 15 deaths from whooping-cough were only one-third of the corrected average number, and included 3 in Shoreditch, 3 in Lambeth, and 2 in Hackney. The deaths from enteric fever, which had averaged 10 in the last four weeks of the five years 1911-15, fell last month to 3, of which 2 belonged to the City of Westminster and 1 to Greenwich. The 100 deaths from diarrhoea and enteritis among children under 2 years of age were 15 above the average; the greatest proportional mortality from this cause was recorded in Hammersmith, Fulham, Chelsea, Islington, Shoreditch, Bethnal Green, and Bermondsey. In conclusion it may be stated that the aggregate mortality in London last month from the principal infectious diseases was 17.6 per cent. below the average.

#### ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING DECEMBER, 1916.

(Specially compiled for THE LANCET.)

CITIES AND BOROUGHS.	Estimated civil population, 1916.	Notified Cases of Infectious Disease.										Deaths from Principal Infectious Diseases.

## THE SERVICES.

### ROYAL NAVAL MEDICAL SERVICE.

To be Temporary Surgeon : H. F. Seymour.

The following appointments have been notified:—Fleet-Surgeons: R. M. Richards and E. B. Pickthorne to the *Victory*; G. M. Eastman to the *Kent*. Staff Surgeons: R. H. St. B. E. Hughes to the *Pembroke* and A. H. Richardson to the *Research*. Surgeons: E. C. Holtom and F. J. R. Cowie to the *Pembroke*. Temporary Surgeons: N. N. Wade to Haslar Hospital; R. M. Barrow to *Swiftsure*; W. H. Sarra to *Cesar*; J. E. Scanlan to *Cochrane*; G. C. Mort to *Pomone*, additional, for Dartmouth College; M. Prior to *Vivid*, additional, for disposal; and H. W. Cooke to *Vivid*, additional, for Plymouth Hospital.

### ARMY MEDICAL SERVICE.

Lieut.-Col. R. Caldwell, from R.A.M.C., to be Colonel, and to be supernumerary.

Temp. Lieut.-Cols. R. Jones and H. G. Barling (Majors, R.A.M.C., T.F.) to be temporary Colonels.

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonels to be acting Colonels whilst employed as Assistant Directors of Medical Services of a Division: H. M. Morton, H. Hewston, W. E. Hudleston.

The undermentioned relinquish the rank of temporary Lieutenant-Colonels on reposing: Bt. Lieut.-Col. FitzG. G. Fitzgerald, Major M. F. Grant, Major A. R. C. Parsons.

Temp. Lieut.-Col. R. J. R. C. Simons (Major R.A.M.C., T.F.) relinquishes his temporary rank.

Captains (acting Lieutenant-Colonels) relinquishing their acting rank on reposing: A. S. Williams D.S.O., A. R. Wright.

Majors to be temporary Lieutenant-Colonels whilst in command of a Casualty Clearing Station: J. M. B. Rahilly, J. G. Bell, D.S.O.

Major W. J. P. Adye-Curran to be temporary Lieutenant-Colonel whilst in command of a General Hospital.

Major R. T. Collins to be temporary Lieutenant-Colonel whilst in command of a Field Ambulance.

Major G. S. Mansfield to be temporary Lieutenant-Colonel while employed as an Assistant Director of Medical Services, Home Forces.

Major W. J. Waters to be acting Lieutenant-Colonel whilst in command of a General Hospital.

Captains (acting Majors) to be acting Lieutenant-Colonels whilst in command of a Field Ambulance: W. I. Thompson, F. Worthington, D.S.O., G. H. Dive, A. S. Littlejohns, A. S. Williams, D.S.O., B. M. O'Neill, D.S.O., J. J. O'Keeffe, A. R. Wright, A. D. Fraser, W. G. Wright, A. G. Wells, T. B. Nicholls, T. T. H. Robinson, F. H. Bradley, J. D. Bowie, F. L. Bradish, T. S. Eves, E. C. Phelan, W. H. Forsyth, E. J. Kavanagh, W. K. Beaman, H. Gibson.

Captains to be acting Lieutenant-Colonels whilst in command of a Field Ambulance: W. B. Burdon, E. D. Caddell, D. F. Mackenzie, G. B. Edwards, C. R. M. Morris, R. Hemphill, W. Egan, C. W. Bowle, J. du P. Langrishe.

Temporary Captains (acting Majors) to be acting Lieutenant-Colonels whilst in command of a Field Ambulance: J. R. C. Greenlees, D.S.O., H. Faulkner.

Temporary Capt. J. la F. Lauder, D.S.O., to be acting Lieutenant-Colonel whilst in command of a Field Ambulance.

Capt. W. I. Thompson to be temporary Major whilst in command of a Field Ambulance.

Temporary Captains to be temporary Majors: N. H. Mummary, F. C. Hart-Smith, J. R. Lee.

F. A. G. Jeans to be temporary Honorary Major while employed with No. 6 British Red Cross Hospital (Liverpool Merchants' Mobile).

Temporary Lieutenants to be temporary Captains: J. L. Whatley, G. A. Hayman, T. Forsyth, C. Witts, C. G. Lambie, A. S. Sieger, W. D. Cruckshank, J. P. MacDonald, F. W. Rigby, J. H. Crofton, W. E. Hills, W. Parker, T. W. B. Morton, H. C. W. Allott, A. W. Allen, J. Welsh, D. Kennedy, W. Darlington, O. V. Burrows, J. Appleyard, J. T. O'Boyle, G. A. MacFarland, C. D. Holdsworth, J. G. Craig, C. F. Rumsey, H. J. Nightingale, H. G. Smith, L. Fraser, W. Duffy, T. H. Twigg, L. D. I. Graham, T. L. Price, D. M. Clements, H. M. Vickers, H. Goodman, D. M. Moffatt, W. H. Blakemore, W. Hamilton, F. M. Murray, G. Thomson, L. Levene, P. E. Barrow, P. A. B. Clark, M. Chadwick, D. W. Daniels, J. S. Dunn, G. C. Linder, R. A. Johnston, J. McIntyre, F. L. Hill, W. A. R. Michell, J. H. Egbert, W. G. Macdonald, R. S. Dollard, H. E. Bloxsome, S. A. D'Arcy, F. Hannigan, O. Carlyle, W. C. Menzies, H. H. Fisk, D. H. Berry, C. S. Vartan, J. K. Davies, W. Wilson, F. M. Byrne, J. Smith, R. Proctor, G. S. Clancy, G. T. Baker, J. B. MacKay, C. A. Dupont, J. C. A. Ridgway, H. G. Baynes, H. C. Watson, J. D. Robertson, H. F. Sheldon, J. W. Weaver.

Lieut. A. R. Wrightman, from 3rd Northern General Hospital (T.F.), to be temporary Lieutenant.

To be Lieutenants and granted the rank of temporary Captain: Temp. Captains: G. D. Jamieson, D. W. Palithorpe, St. J. D. Buxton, S. Arnott, T. L. Fraser, L. G. Bourdillon, G. A. Lilly, J. Sainsbury, G. D. Robertson, H. D. F. Brand, J. P. Little, C. J. O'Reilly, D. C. Monro, W. Foot, F. C. K. Austin, G. A. E. Argo, S. S. Crosse, R. W. Galloway, G. D. Harding, J. A. Andrews, H. J. Couchman, R. C. Robertson, W. A. Sneath, A. L. Aymer, A. N. Minns, D. Pottinger, D. Bell, D. G. Cheyne, P. A. Opie, A. S. Taylor, H. C. Godding, D. W. Beamish, W. L. E. Reynolds, H. A. Rowell, O. B. Pratt, J. H. Boag, C. R. Dudgeon, H. E. A. Boldero, R. C. Matson, H. R. Sheppard, R. L. Ritchie, E. S. Cuthbert, J. La F. Launder, D.S.O., T. H. Sarsfield, J. F. Bourke, H. J. Bower, A. F. G. Guinness, Captain from R.A.M.C. (T.F.): R. E. Barnsley. Captains from R.A.M.C. (Special Reserve): E. Davies, T. J. Kelly, R. J. Clausen, C. McN. McCormack, E. F. W. Grellier, O. Hairsine, A. B. Preston, R. Ellis, F. G. A. Smyth, J. C. A. Dowse, C. O. Shackleton, F. P. Freeman, A. M. McCutcheon, H. H. Mulholland, A. C. Jebb, E. B. Marsh, C. W. Treherne, J. H. Pendered, W. W. MacNaught, J. P. Little, H. A. Harbison, W. G. Shakespear, A. L. Robb, E. Catford, A. F. J. Patterson, C. J. D. May, T. P. Rankin, W. C. Hartgill, T. F. Kennedy, K. A. M. Tomory, J. S. Sloper, C. Wilson, H. N. Stafford, R. I. Sullivan, R. A. Anderson, F. M. Lipacomb, H. P. Rudolf, D. N. Macleod, G. B. Hadden, R. P. Cormack, G. S. Pirie, W. K. Campbell, G. H. Haines, R. B. Myles, R. R. Thompson, A. E. Richmond, E. Jamieson, J. E. Brooks, W. H. A. D. Sutton, G. T. Gimeléte, W. L. A. Harrison, F. R. S. Shaw, R. Stowers, O. D. Jarvis, J. A. Binning.

H. P. Thompson to be temporary Honorary Lieutenant.

Temp. Major John M. Atkinson relinquishes his commission on account of ill-health.

Temporary Captains relinquishing their commissions: F. A. R. Hacker, A. Dingwall Fordyce, G. Norman, G. A. Finlayson, G. W. Thompson, N. D. Bardsell, J. R. H. Walker, E. J. Stubbs, R. R. Forbes, J. R. Dobbin, J. A. Gentle (on account of ill-health).

Temp. Hon. Capt. W. Gennell, H. Bowring, J. Beckett, and W. D. Copplestone relinquish their commissions.

Temporary Lieutenants relinquishing their commissions: J. C. Forbes, A. W. Brodrrib, L. W. May, T. F. Wilson, C. J. R. Joyce, J. J. McMillan, C. K. Stevenson, J. McDonald, E. Rommel, R. J. Bethune, N. H. Austin, J. F. MacLeod, M. G. Pettigrew, J. Bowen-Jones, J. A. K. Griffiths, C. H. G. Ross, G. Stowell, C. H. Ferguson, C. H. Phillips, J. Pender, T. H. Clarke, H. L. Askham, A. Barrett, H. P. Thompson, S. D. Bridge, A. O. Evans, J. G. Bell, F. M. Bishop, R. A. McNeill, R. T. Slinger, W. H. Broughton, A. E. Clark, H. A. Watney, G. R. Potter, J. C. Mead, J. M. Hermon, W. J. McL. Baird, W. H. Hodgson, H. M. Mills, J. W. Hilliard, T. A. Mayo, G. Kee, N. Navarra, H. Harrison, H. F. Johns, W. Bligh, H. W. M. Strover, P. Stocks, W. J. Asby, V. Colmer, H. E. Brown, P. A. Nightingale, A. T. Thompson, J. D. Stewart, C. J. Pentland.

#### SPECIAL RESERVE OF OFFICERS.

Captains (acting Majors) to be acting Lieutenant-Colonels whilst in command of a Field Ambulance: M. R. Taylor, D. C. Barron, K. D. Murchison.

Capt. A. H. Habgood to be acting Lieutenant-Colonel whilst in command of a Field Ambulance.

Lieutenants to be Captains: J. Cullenan, C. O. J. Young, N. A. Martin.

To be Lieutenants: F. K. Hayman, from Bristol Contingent, O.T.C.; T. Stanton, from Dublin University Contingent, O.T.C.; G. E. Archer, from University of Manchester Contingent, O.T.C.; W. Burridge.

#### TERRITORIAL FORCE.

Lieut.-Col. H. G. Barling is now seconded whilst holding a temporary commission in the Army Medical Service.

Major (Temp. Lieut.-Col.) G. M. Hetherington relinquishes his commission on account of ill-health.

Major A. N. Davis resigns his commission on account of ill-health, and is granted the honorary rank of Major.

Capt. H. Beeney relinquishes his commission on account of ill-health, contracted on active service, and is granted the honorary rank of Captain.

Capt. F. C. Bentz relinquishes his commission on account of ill-health caused by wounds, and is granted the honorary rank of Captain.

Lieutenants to be Captains: N. R. Williamson, A. J. A. McCabe-Dallas, A. M. Jones, T. B. McKee, S. K. McKee.

Attached to Units other than Medical Units.—Lieut. J. A. Hartley to be Captain. Major J. F. Crombie to be temporary Lieutenant-Colonel whilst commanding a Field Ambulance.

#### INDIAN MEDICAL SERVICE.

Lieutenant-Colonel to be Colonel: W. E. Jennings.

Lieutenant-Colonels to be temporary Colonels: G. B. Irvine, C. N. C. Kimberley.

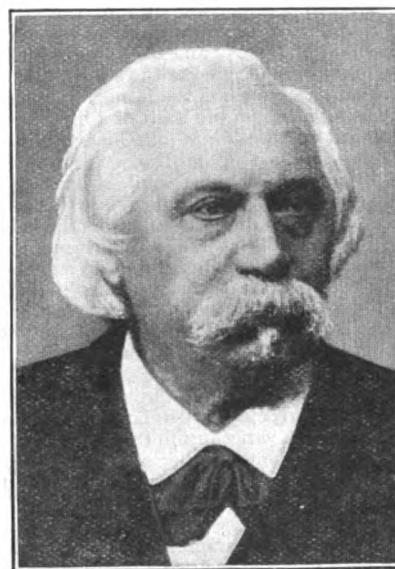

To be Lieutenants: I. D. Grant, A. H. Brown, E. Cotter, H. E. Murray.

## Obituary.

### JEAN BAPTISTE AUGUSTE CHAUVEAU.

Auguste Chauveau, whose death in his ninetieth year we recorded last week, had outlived all his famous co-workers of earlier years. E. J. Marey had long predeceased him, while Charles Bouchard, his coadjutor in founding the *Journal de Physiologie et de Pathologie Générale*, died in October, 1915. Associated thus in the direction of an influential journal, the spheres of activity of Bouchard and Chauveau were yet widely different: the former was an eminent and well-beloved physician, the latter will be remembered as a many-sided biologist and one of the makers and masters of physiology during the latter half of last century. He was also a great comparative pathologist, doing pioneer work on various contagions, including tuberculosis, which had an intimate bearing on practical and preventive medicine. His energies, however, were not confined to this borderland between pathology and medicine, for he became a fine exponent of veterinary medicine.

Auguste Chauveau was born at Villeneuve-le-Guyard (Yonne) on Nov. 23rd, 1827, and, like many other provincials, gravitated to Paris, where he studied at Alfort—

AUGUSTE CHAUVEAU.

the great veterinary school just outside Paris—and also in the Faculty of Medicine of Paris, as well as at the Veterinary School of Lyons. He was elected on the staff of the Lyons Veterinary School at the age of 21, and ultimately its director in 1875. His wide knowledge of the subject led to his appointment as inspector-general of the Veterinary Services in France. Later on his keen interest in the advancement of physiology and pathology found a new and wider sphere on his appointment as professor of comparative pathology at the Natural History Museum in Paris, where he built an entirely new institute fitted for the study of comparative physiology and pathology. In Paris Chauveau took an active interest in all that went on in the medical societies. He was a member of the Institute at the Academy of Sciences, where he sat not as a physiologist but in the agricultural economy section, just as Pasteur did not sit as a chemist but as a representative of mineralogy. He was also a member and regular attendant at the Academy of Medicine, as well as at the Society of Biology, of which he was at one time president. At these gatherings his genial presence and bonhomie, his interest in all newer scientific work, and also in the younger workers themselves, made him a highly popular figure.

Chauveau's published writings cover a very extensive field. Some of the more important may be mentioned. In 1868 he

published his "Nature des Virus," showing the "corpuscular state" of the virulent agents and the inactivity of the fluid in which they float. This was based on an earlier essay, entitled "Sur la Non-spontanéité des Maladies Virulentes." In the same year appeared a series of important studies on tuberculosis dealing with its virulence, the transmission by way of the digestive tract, and its contagious character in animals and man. Papers followed on the mechanism of natural contagion, on the attenuation of viruses and preventive inoculation, on the presence of pathological microbes in blood, in persons apparently in good health, on cow-pox and its relation to small-pox. Puerperal septicæmia and gangrene were also studied. While still at Lyons he published his "Traité d'Anatomie Comparée des Animaux Domestiques," the second edition of which, revised and augmented by S. Arloing—at that time professor in Toulouse—was translated into English by the late Professor George Fleming and published in 1873. Bio-chemical problems also attracted him. He and his pupils did work on glycogenesis and on the formation and use of sugar in the organism. With Kaufmann in 1886 he attempted to solve the problem whether circulating sugar can be immediately utilised by active muscles. They came to the conclusion that an active muscle, such as the masseter of the horse, uses about three and a half times as much blood sugar as the corresponding resting muscle—results confirmed later by Quinquaud in 1892 and by Morat and Dufourt in 1892.

It is, however, as the explorer of the movements of the living heart that Chauveau will probably be best remembered. As a contemporary of Ludwig and co-worker with Marey, his earliest researches were devoted to the study of the different phases of the cardiac cycle and the intracardiac pressure, the observations being made on the heart of a horse by means of the now classical cardiac sound of Chauveau and Marey, utilising Marey's method of air-transmission of variations of pressure by means of tubes and recording tambours. Probably few of the younger physiologists in this country have seen such an experiment, but as recently as the International Congress of Physiologists at Liège Chauveau repeated this famous demonstration. The horse quietly munched its oats in the stable below, while the movements of its heart were recorded in the auditorium above. The main results of this work were published in a little brochure, entitled "Nouvelles Recherches expérimentales sur les Mouvements et les Bruits normaux du Coeur," by Baillière in 1856. Fuller details may be found in Marey's "La Circulation du Sang." In 1860 Chauveau constructed, with Lortet, the haemodynamograph to measure the variations in the velocity of the blood in large arteries. Amongst other results they recorded the increase of velocity of the blood during systole of the left ventricle, and the increased rate of flow in the carotid artery during mastication.

Chauveau's personal characteristics made him widely known outside his immediate circle. He had a gracious and commanding presence. His massive, almost leonine, head, set on a powerful and strongly built body, made him a striking figure on public occasions. He was a great friend of the late Sir J. Burdon-Sanderson, and some of their work was done in the same region of physiology. Allusion has already been made to his catholicity of outlook and his encouragement of the work of younger investigators. Chauveau's long life was dedicated to the advancement of knowledge, and his memory will live as truly in the work which his encouragement and inspiration produced at the hands of his pupils as in his own many-sided achievements.

#### MARY BIRRELL DAVIES, L.R.C.P., L.R.C.S. EDIN., L.F.P.S. GLASG.

LIVERPOOL has lost a remarkable member of the medical profession by the death of Mary Birrell Davies, which occurred on Dec. 30th, 1916. She was not only a most active practitioner, but exerted a wide influence for the good of the people by her personality and organising ability. Miss Davies had a wide *clientèle* among all classes of women in a professional capacity and also as a sympathetic advisor and counsellor. For many years she had interested herself in matters having to do with social welfare and her kindness and gentleness, combined with strength of character, gave her an influence which she used to the uttermost.

Immediately after the outbreak of war she initiated the Women's War Service Bureau and organised it in conjunction

with Mrs. Herbert Rathbone, then the Lady Mayoress. This organisation has done and is still doing splendid work. In October, 1914, she went to France and did good service at Boulogne, but her failing health compelled her return towards the end of the year. Her next war work was to start and to carry into effect the Soldiers' and Sailors' Club in Lime-street, where she worked as supervisor for several months. Finally she superintended the organisation and equipment of Lady Sefton's Hospital for Officers at Croxteth Hall and remained there as resident administrator until a few weeks before her death, when her progressive illness rendered it no longer possible for her to continue there.

Among other departments of public work with which Miss Davies was connected may be mentioned the Girl Guides movement. She was instrumental in setting this going and was appointed commissioner, a position which she held to the end and in which she did invaluable work, not only in Liverpool, but for the movement generally. She was a member of the Victoria Women's Settlement, and acted as adviser to the Juvenile Employment Section of the Labour Exchange. In connexion with the Women's Patrol movement she spoke at many of the meetings, and she was an active member of the Liverpool Medical Institution Committee for Combating the Venereal Diseases from the time of its inception in 1913. Under the Home Office she held the office of inspector of children's institutes under the Children Act. Among women of the working classes she was well known and frequently addressed them with the object of inducing them to exert their responsibilities, more especially in the direction of bringing up their children to recognise the physical as well as the moral benefits of a well-ordered life.

Any appreciation of Miss Davies's life and work would be incomplete without reference to her genius for friendship with other women. "Her closest friends were so almost comically different and unlike each other that there didn't seem room for jealousy, and it only shows how many-sided she was that she needed us all to companion her properly. In her relationships towards men her infinite tact and personal magnetism, combined with her professional ability, established a kindly feeling of comradeship which did much to bring about those good relationships which have for long existed between medical men and their professional sisters in Liverpool." (We quote from the letter of a Liverpool friend.)

She was among the bravest of women. For several years she had been under the shadow of a mortal and painful illness, which she never permitted to interfere with the work that she carried out to the end with devotion and with all the energy of which her diminishing strength was capable.

**THE University College of South Wales and Monmouthshire is endeavouring to raise a sum of £100,000 for the erection of laboratories for work in relation to local industries.**

AT an inquest in the City on a woman munition-worker who died of T.N.T. poisoning in St. Bartholomew's Hospital the jury added a rider to their verdict suggesting that munition-workers should be medically examined once a fortnight.

**A RURAL ORGANISATION COUNCIL.**—With the objects of increasing the supply of home-grown food and co-ordinating and preventing the overlapping of societies concerned in improving the conditions of rural life in the homeland, a Rural Organisation Council has been formed. Some of the leading societies concerned with agricultural organisation, rural housing, rural education, local government, handcrafts, and industries have already joined the Council, which, by promoting a regular interchange of opinion between itself and the constituent societies, will, it is hoped, strengthen local efforts. A central organisation should be better able to direct collective action. As is pointed out in a circular asking for a sum of money proportional to the importance of the objects in view, the war now gives an excellent opportunity for organising a better development of the conditions of rural life against the day of disbanding, when vast numbers of sailors and soldiers will be set free, many of whom may desire a life on the land. The temporary office of the new Council is at one of the constituent societies, the National Land and Home League, Queen Anne's Chambers, Westminster, S.W., of which Lord Henry Bentinck, M.P., is the president and Lord Saye and Sele the chairman. Mr. T. Hamilton Fox is the honorary secretary of the Organisation Council.

## Correspondence.

*"Audi alteram partem."*

### A HOME MEDICAL SERVICE FOR THE TREATMENT OF SOLDIERS.

*To the Editor of THE LANCET.*

SIR.—In a leading article in your issue of Jan. 13th, referring to a proposal that greater use should be made of the part-time services of civilian doctors for the treatment of sick and wounded soldiers in this country, you say (p. 68): "We believe that in this way an economy of personnel could be effected, and more medical men found to meet the demands of the Director-General of the Army Medical Service."

I am confident that your belief is as well founded as it is widely held by large numbers of men qualified to express an opinion on the question. At the same time you refer to the well-known difficulties attached to the proposal. I believe that these difficulties are only on the surface, and would disappear if they were boldly faced. There certainly should be no difficulty in obtaining men for this home service. A properly constituted authority set up by Government and empowered to offer a moderate remuneration for the work undertaken would at once be inundated with offers, not merely of part-time but of whole-time service, by medical men who on account of age, nationality, partial invalidity, or commitments to their civilian patients could not be regarded as eligible for commissions in the R.A.M.C. The difficulty here would merely be one of selecting those best fitted for the work by their professional attainments or most suitably situated locally to carry out together their hospital duties to the soldiers and their domiciliary duties to their civilian patients.

If the personnel of the constituted authority were properly chosen, not only could these tasks of selection be well performed, but the professional work to be carried out could be wisely allocated according to the type of practice, general, consultant, or specialist, in which the applicant had previously been engaged. With such a volunteer home service enrolled there should be no difficulty in providing from it an adequate staff for any hospitals already, or hereafter to be, established for the treatment of sick and wounded soldiers in this country. There are already numerous Red Cross and private hospitals for soldiers running smoothly and efficiently, which are staffed by men of the type who would constitute this service, the only difference being that these staffs have been individually appointed to these hospitals, and do not form part of any centralised service. The existence of a central controlling authority would promote efficiency and make it easy to meet any troubles that from time to time might arise, and to remove and replace an inefficient member of the staff.

Nor should any difficulty be found in arranging for members of this home service and members of the Royal Army Medical Corps to work side by side in hospitals in which this seemed a desirable plan. Civilian doctors without commissions, part-time civilian doctors with *à la suite* commissions, and R.A.M.C. officers are conjointly staffing many hospitals now. But if this is not thought desirable, some hospitals could be staffed entirely by the home service and others by the R.A.M.C. It should not be difficult for the authorities of the Army Medical Service to select the hospitals whose transference to home service staffs would set free the largest number of R.A.M.C. officers for duty abroad. There should be no difficulty in finding funds for the payment of this service or in fixing the remuneration of its members. The cost would certainly be considerably less than that of remunerating a corresponding number of commissioned officers. There would be no need to make provision for pensions.

If I have by chance unduly minimised the difficulty of solving some of the problems indicated above there can certainly be no doubt that they are collectively incomparably easier of solution than is the problem of providing additional medical men for the Army, without dangerous depletion of the medical services of the civilian population, by any other means than by the greater use of the part-time services of civilian doctors for the treatment of soldiers. Perhaps, however, the difficulty you, Sir, have

in mind is that of persuading the Government that this step is necessary or of securing the cordial co-operation of the authorities of the Army Medical Service. If so, I venture to think that again these difficulties are exaggerated. The Government is now thoroughly alive to the fact that the war is not to be won by the fighting forces alone, but that the needs of munition workers and food producers must also be considered. The War Office, too, is learning to accept gratefully any relief from responsibilities which can be safely entrusted to others.

With the powerful assistance of the medical press there should be no insuperable difficulty in persuading the Cabinet of the urgent need of the prompt establishment of a home medical service for the hospital treatment of sick and wounded soldiers in this country.

I am, Sir, yours faithfully,  
London, N.W., Jan. 15th, 1917. LAURISTON E. SHAW.

### THE DEFINITION OF ACUTE ALCOHOLISM.

*To the Editor of THE LANCET.*

SIR.—In a letter in your issue of Jan. 13th Dr. Chalmers Watson draws attention to the curious fact that, while drunkenness amongst women in Edinburgh, as measured by the police returns, decreased materially last year, there was at the same time a large increase in the number of female patients admitted to the Royal Infirmary suffering from "acute alcoholism." It would be interesting, and might, perhaps, help towards the explanation of this apparent paradox, if Dr. Watson would indicate whether there has been an alteration in the type as well as in the number of the cases included under this latter heading—whether, for instance, cases of delirium tremens have increased in the same proportion as the other conditions grouped with it under the general denomination of "acute alcoholism." Amongst the various suggested indices of excessive drinking statistics of delirium tremens have the very decided advantage that they refer to a tolerably well-defined and easily recognisable clinical condition, and are, therefore, less liable to disturbing influences arising from the differing judgments and points of view of different observers. The official returns published in the daily press show that statistics of this disease have been found to be a useful and reliable means of gauging alcoholism in England; it would be in accordance with accepted medical views to anticipate that they would be even more valuable in Scotland, where spirits are the predominant form of alcoholic beverage.—I am, Sir, yours faithfully,

London, Jan. 17th, 1917. W. C. SULLIVAN, M.D. R.U.I.

### DENTAL SURGERY AND INJURIES OF THE JAW.

*To the Editor of THE LANCET.*

SIR.—In the *Annus Medicus* of your issue of Dec. 30th the treatment of war injuries of the jaws was discussed under the heading of Dental Surgery. This raises an important question—the question of personnel. The principles to be observed in the treatment of fractures are fundamentally the same whatever bone be involved. The end in view is the attainment of firm union without deformity and without loss of function. The means to be employed will be largely determined by anatomical factors. It is as regards this anatomical factor only that a fractured jaw differs from a fractured femur. The means to the desired end may briefly be classified as mechanical and surgical, used more particularly in the narrower sense of operative. The dental surgeon is fitted by his training and experience to devise and construct mechanical apparatus for the efficient and accurate retention of fractured fragments in their normal positions. In the simpler forms of fracture, by the employment of such means as his daily work has made him familiar with, he may attain good results and may rightly be charged with the sole responsibility for the conduct of the case. A great number of the fractures occasioned during this war have not been, and will not be, of this simpler type. Comminution, loss of bony substance, laceration and loss of soft parts are only too frequent. In the presence of these complicating factors the dental surgeon must necessarily feel himself at a loss. There is nothing in his previous experience to guide him; he is

unacquainted with the behaviour of analogous lesions in other parts of the body. Left to himself, he utilises, and rightly so, only such methods as he feels conscientiously entitled to employ. My contention is that these methods are totally inadequate for the efficient treatment of complicated cases. Most dental surgeons will readily grant the truth of this contention, and would only too gladly welcome active co-operation and collaboration with their respective surgeons. The attitude of surgery in this matter has exhibited a tendency to two extremes. In the early days of the war the dental surgeon was ignored; it is now becoming more and more customary for surgeons to refer jaw injuries to the unassisted care of the dentist. The results under the former system were almost consistently bad; the results under the latter system are likely to be equally unsatisfactory as regards these severer types of injury. Surgical conditions should be dealt with by surgeons. War injuries of the jaw should no more be treated by dental surgeons alone than should the treatment of such injuries be discussed exclusively under the head of dental surgery.

Active collaboration between surgeon and dentist makes for the good of the patient and for progress, and until such time as the importance of this is universally recognised and acted upon so long will discreditable failures continue to occur.

I am, Sir, yours faithfully,

Queen Anne-street, W., Jan. 12th, 1917. PERCIVAL P. COLE.

## THE PHENOMENA OF ANAPHYLAXIS.

*To the Editor of THE LANCET.*

SIR.—As it does not seem to be generally known, it may be of use to point out that after serum injections anaphylactic symptoms coming on at once and serum rashes coming on after an interval are rapidly controlled by subcutaneous injections of pituitrin. In anaphylaxis 1 c.c. given at once relieves the collapse and spasm of the bronchioles within a few minutes. The dose should be repeated if the symptoms show any sign of returning. A similar plan is equally successful in serum rashes.

I am, Sir, yours faithfully,

W. M. CROFTON, M.D. N.U.I.  
Laboratory of Special Pathology, University College,  
Dublin, Jan. 14th, 1917.

## THE NOMENCLATURE OF "INTERNAL SECRETION."

*To the Editor of THE LANCET.*

SIR.—I hope and think that on reflection Sir Edward Schäfer will regret the arrogant tone he adopted in his letter in your issue of Jan. 13th concerning the nomenclature of "Internal Secretion." It is quite unworthy of his high position. I regret extremely that, in the circumstances he has created, an effective answer must necessarily contain a few remarks that will perhaps increase his displeasure. I hasten to apologise in advance, for controversy is better carried on in a spirit of mutual consideration.

To deal first with the last sentence in his letter. Professor Schäfer asserts, "I have at least as good a right as Dr. Blair Bell to suggest an appropriate nomenclature for what is after all to some extent my own progeny." With regard to the "right" he claims, I am sure no one will deny that everyone who has worked at the subject has an equal right in this matter. I have never hinted anything to the contrary. As to the assertion that the internal secretions are the progeny of Sir Edward Schäfer—well, I hardly know what to say; it seems unnecessary to say anything, so common is the knowledge that they were brought into existence long before Sir Edward Schäfer was born. If by "to some extent" he means to pay a well-deserved tribute to the numerous able collaborators with whom he has worked, why put it in such a back-handed and vainglorious manner? If by this qualification he means that he has helped to wash and nurse a lusty infant, I am sure all will agree that he has done well in the matter; but even this does not give him the right to claim the offspring as his own.

Now as to the subject under discussion. Let me say at once that I do not think my remarks regarding Sir Edward Schäfer's terminology can be described as "censure"—that is a strong term, and one which implies far more than could be extracted from my words. Besides, if he will look again at my letter he will find that I do not, as he states, attribute

the word "endocrine" to him. I am glad, however, that he tacitly admits that "endocrine" is a badly formed word. Indeed, it would hardly be a greater classical crime to make it mean "internal hair" instead of the present interpretation. This being so, I am surprised that one who later on tries to trip me up on a somewhat similar point, should demand its perpetuation.

With regard to Sir Edward Schäfer's objection to my suggested terms "hormopoietic" and "hormopoiesis," I have already said I do not approve of "endocrinist," even though my sense of correct word-formation has compelled me to use it in the past in preference to "endocrine." I think that all will admit that "hormopoiesis" is more euphonious than "hormonpoiesis," which at first I thought of suggesting; and I think that there are plenty of instances to be found of such shortening—for example, "antacoid." I take it that for philological purposes the root "horm-" is the one common to the noun "hormone" and the verb from which it was derived; but by all means make the word "hormonpoiesis" if it will help the uninitiated. Further, I am afraid I must accuse Sir Edward Schäfer of having no imagination, for a very little would have shown him that even if the root "horm-" were derived from *δρμος* it would not be inappropriate, for do not the hormones connect—link up—the tissues of the body; Q.E.D., as Euclid used to say. Again, I must emphasize the fact that it would be an untold advantage, especially to students, to have some direct sequence in our terminology of the subject.

With regard to the complaint of my "following most authors" and limiting the term "hormone," perhaps the following statements from my Arris and Gale lectures may make quite clear my position, which, oddly enough, appears to be even less limited than that of Sir Edward Schäfer: "It is probable that every cell in the body is a ductless gland, and has some influence on the life and functions of the rest. .... The aggregations of specialised cells for the regulation of the body metabolism, which are known as the ductless glands .....".<sup>1</sup> Further, I can assure Sir Edward Schäfer that I am quite familiar with his own small work on "The Endocrine Organs" and with the classical paper of Bayliss and Starling to which he refers in his book and letter. Unfortunately, I am too well acquainted with the paper of Bayliss and Starling for Sir Edward Schäfer's comfort, for had he been as well acquainted with it as he professes he would have avoided a mistake, of which, judging from the tone of his letter, he is incapable. There is no mention of the word "hormone" or of the term "chemical messenger" in this paper. Since there are only about a dozen references in the whole volume such a mistake is inexcusable, and to make capital of it against me is ludicrous.

I have already said that there is nothing against the words "chalone" and "antacoid" as verbal trifles, but they are superfluous, and tend to burden the nomenclature of the subject. But to say that the provocation or production of inhibition—Sir Edward Schäfer calls it "provoking prevention"—is a contradiction in terms is singularly unfortunate. Here, too, a little imagination would probably have brought as much understanding as is possible in regard to inhibition produced by hormones—a phenomenon, indeed, which is little understood, even if it be admitted.

I am, Sir, yours faithfully,  
W. BLAIR BELL.

## THE LIQUOR TRAFFIC AND THE FOOD QUESTION.

*To the Editor of THE LANCET.*

SIR.—There is no magic, necessarily, in State control—only wise enactments thereafter would achieve the avowed object. My point is that such legislation, if carefully thought out and really sane and practicable, can just as well be applied without purchase of the Drink Interest as with it. This is most important from the point of view of husbanding the nation's finances and avoiding the colossal addition to the National Debt which purchase would mean.

I am, Sir, yours faithfully,  
Whitehall Court, S.W., Jan. 13th, 1917. HENRY CURTIS.

# The War.

## THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

### *Wounded.*

- Capt. J. Crawford, R.A.M.C.
- Capt. D. W. F. Jones, R.A.M.C., attached King's Royal Rifle Corps.

## DEATHS AMONG THE SONS OF MEDICAL MEN.

The following son of a medical man must be added to our lists of those who have fallen during the war:—  
Second Lieut. C. S. Dalziel, Durham Light Infantry, youngest son of Dr. W. Dalziel, of South Shields.

## THE HONOURS LIST.

The following awards to medical officers are announced:—

### *Military Cross.*

- Capt. Edward James Blair, R.A.M.C.

For conspicuous gallantry and devotion to duty. He tended and dressed the wounded under heavy fire continuously for 18 hours. He set a splendid example of courage and determination throughout.

- Capt. Hawtrey William Browne, R.A.M.C.

For conspicuous gallantry and devotion to duty. He made a tour of five regimental aid posts under very heavy fire and carried in many wounded men. He set a splendid example throughout.

- Temp. Capt. William George Thomas Hepplewhite, R.A.M.C.

For conspicuous gallantry and devotion to duty. He worked unceasingly day and night supervising his bearers, clearing the wounded under very heavy fire. He set a splendid example throughout.

- Temp. Capt. Herbert Bruce Low, R.A.M.C.

For conspicuous gallantry and devotion to duty. He dressed the wounded and supervised the work of the bearers under very heavy fire. He set a splendid example of courage and coolness throughout.

- Capt. John Wright Malcolm, R.A.M.C., Spec. Res.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in constantly directing bearer squads under heavy fire. On another occasion he rescued several men who were buried.

- Temp. Capt. Victor Harold Mason, R.A.M.C., East Yorks Regiment.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in tending and dressing the wounded under very heavy fire.

- Temp. Capt. Lloyd Remington Meech, R.A.M.C.

For conspicuous gallantry and devotion to duty. He worked continuously for 48 hours collecting wounded under very heavy fire. He set a splendid example throughout.

- Temp. Lieut. Alexander Gordon Peter, R.A.M.C.

For conspicuous gallantry and devotion to duty. He tended and dressed the wounded under very heavy fire, displaying great courage and determination throughout.

- Temp. Lieut. Albert Edward Sutton, R.A.M.C.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in tending the wounded under heavy fire. He worked single-handed all night in an advanced post.

- Temp. Capt. Harold Ernest Pierpoint Yorke, R.A.M.C.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in tending the wounded under very heavy fire. Later, although himself wounded, he continued to carry out his work.

- Capt. William Malloch Hart, Canadian A.M.C.

For conspicuous gallantry and devotion to duty. He displayed great courage and skill in evacuating wounded under most trying conditions. On one occasion he worked for several hours in the open under heavy fire attending to the wounded. He has previously done fine work.

- Capt. Tom Welsh, S. African Med. C., attached South African Infantry.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in organising and leading stretcher parties under very heavy fire.

It is officially announced that the name of Capt. Robert Burgess, R.A.M.C., is to be deleted from the list of those to whom the Military Cross is awarded (THE LANCET, Jan. 6th, 1917, p. 38).

A SUPPLY dépôt for the St. John Ambulance Brigade has been opened at Halkyn House, Belgrave-square, S.W.

## OBITUARY OF THE WAR.

### ERNEST HOWE, M.B., CH.B. VICT., LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant E. Howe, who died last month of wounds contracted on active service, was 30 years of age. He received his medical training at the Owens College, Manchester, and Manchester Royal Infirmary, graduating M.B., Ch.B. of Victoria University in 1909.

After holding the appointment of house physician at Manchester Royal Infirmary he settled in practice at Hazel Grove, near Stockport, until the need for medical officers in the R.A.M.C. became pressing, when he applied for a commission, which he obtained in October, 1916. He was sent out to Salonica and was resting after taking his turn in the trenches when he was wounded in several places by fragments of shell during an air raid.

One portion penetrated the chest and death rapidly resulted from shock. Lieutenant Howe had not practised long in Hazel Grove, but had already, by his devotion to work and consideration for others, established himself in the esteem of his patients and professional colleagues. He leaves a widow and two young children.

### BENJAMIN RICHARD ROBERTS, L.R.C.P. & S. EDIN., L.F.P.S. GLASG., LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant B. R. Roberts, who was killed in action in France early in August last, was educated at Queen's College, Galway, and at the Royal College of Surgeons, Edinburgh, where he took the triple qualification of the Scottish Colleges in 1898. Three years later he went out as civil surgeon attached to the R.A.M.C., serving in this capacity during the Anglo-Boer War. Shortly after the declaration of peace in 1902 he was appointed acting district surgeon at Barberton, and subsequently medical officer in charge of the native refugee camps at Kroonstad and Vereeniging. In November, 1903, he joined the medical staff of the Central South African Railways in the Orange River Colony, and in the following year was sent to Johannesburg as additional railway medical officer, a post which he filled until early in 1916, when he volunteered for active service in France. His death was due to a shell

explosion, and was instantaneous. The news of Lieutenant Roberts's death came as a great shock to the many railway men who had known him, and amongst whom his genial kindness and skill made him deservedly popular. He took a keen interest in Volunteer work, and was for years medical officer to the Railway Volunteer Engineering Corps as it then existed. Lieutenant Roberts leaves a widow and two young sons, with whom much sympathy is felt.

## THE CENTRAL MEDICAL WAR COMMITTEE.

At a meeting of the Central Medical War Committee held on Wednesday afternoon last it was decided to join with the Committee of Reference of the English Royal Colleges and the Scottish Medical Services Emergency Committee in submitting a memorandum to the Director of Public Services on the subject of the organisation of the whole of the medical profession for the purposes of the war and of the existing national circumstances, and asking for an early interview.

## THE SUPPLY OF KNITTED ARTICLES FOR THE FORCES.

The supply of sweaters and other knitted articles absolutely needed for the comfort of the men in the Navy and Army is running short, not probably through decrease of effort so much as because the numbers to be supplied have happily much increased. In these circumstances we call the attention of our readers to the following letter which we received last week from Mr. John Penoyre, 8, King's Bench-walk, Inner Temple, London, E.C.:

It has been my good fortune to transmit to the men in the field some 32,000 sweaters since the war broke out. Sir Edward Ward, the Director-General of Voluntary Associations, now asks if, without letting the sweater industry go down, I could "do the same for the men's mufflers, of which a very great quantity are wanted at once." The sweater pattern, easy and economical, is to be had here for asking, but the W.O. formula for mufflers is so short that I hope you may find room for it at once. The muffler should measure 58 in. by 10 in. and be made on two No. 7 needles, taking 10 oz. of fairly thick drab or khaki wool. One knows of the enormous amount of well-considered work that has been done for the men all over the country. I feel, however, that one has but to name the incredible numbers that our armies have recently reached to justify asking this further effort. I am authorised, then, to state that the need for sweaters, mufflers, and all other hall-marked comforts is great and immediate, and that these should be sent either to the Voluntary Organisations Depots throughout the country, or to the D.G.V.O.'s Depot at 45, Horseferry-road, S.W., or to me as above.

When any of our readers are confronted with patients or the friends of patients whose time is not fully occupied it will be useful to bring Mr. Penoyre's movement before them.

## THE EDITH CAVELL HOMES OF REST FOR NURSES.

—Lieutenant-Colonel Sir Richard C. Temple, as chairman of the council for the institution of these homes, recently drew attention to the fact that the officers of H.M.H.S. *Britannic*, then about to proceed to the Near East, had offered voluntarily to make a collection for the homes. Soon afterwards the *Britannic* was torpedoed and some of the staff lost, but the following letter from Captain H. Slater, R.A.M.C., to Sir Richard Temple shows the interest taken by the nursing sisters and medical staff on board:—

St. Brideaux, Devonport.

DEAR SIR.—There was collected on H.M.S. *Britannic* the sum of £13 15s. 1d.; of this I placed £9 8s. 7d. in charge of the Purser, and it went down with the ship, but I hope to get this refunded. In the meantime, I send you my cheque for the balance, £4 6s. 6d. I may say that we had hoped to collect £30, and no doubt we should have done so except for our unfortunate misadventure. A very general interest was shown in the proposed homes by the nursing sisters and the troops of the R.A.M.C. Our most energetic collector was Lieutenant J. Cropper, R.A.M.C., who lost his life, being cut to pieces by a propeller.

The example of the staff of the ill-fated *Britannic* in respect of the Edith Cavell Homes is one that we hope may be widely followed.

THE NEW ONTARIO MILITARY HOSPITAL.—The opening of the new Ontario Military Hospital at Coburg, Ont., in what was once Victoria College, the forerunner of Victoria University, Toronto, is fresh evidence of the enterprise of the Ontario Government for the welfare of returned soldiers. The hospital has been established by the Ontario Government for the treatment of returned soldiers who are suffering from mental disease due to shell shock or other causes, and is under the supervision of the Canadian Hospitals Commission. Dr. F. S. Vrooman, of the Brockville Hospital for the Insane, is medical superintendent, and the other members of the staff have been drawn from institutions in the province. The hospital is equipped with continuous baths, radiant-light and radiant-heat cabinets, electric baths, Scotch douche, needle, shower, and sitz baths, and has

accommodation for 150 patients, although only 70 beds are occupied at present. So far some 40 per cent. of the cases have been discharged cured or much improved, others have been removed to institutions for permanent care. The hospital is claimed to be the first of its kind in the Empire outside the British Isles.

HEALTH OF THE GERMAN ARMY.—A wireless message from the Berlin Admiralty gives health statistics for the German Army during the second year of war. The message states that small-pox was non-existent, typhoid had diminished by three-quarters, dysentery and cholera by one-third. The incidence of phthisis and pneumonia had sunk to about one-half. Of the wounded, 70 per cent. returned to the front and 6 per cent. were unfit for further military service. The mortality in the base military hospitals amounted to 1 per cent. The total number of soldiers blinded during the war was 1250.

## Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the quarterly examination in Practical Pharmacy held on Jan. 11th the following candidates were successful:—

Hector Demetrius Apergis, Guy's Hospital; Edwin Alfred Clegg, Middlesex Hospital; Alan Andreas Cockayne, Cambridge University and St. Thomas's Hospital; William Arnold Clements, Birmingham University; Arnold Edgar Colle, Cambridge University and Middlesex Hospital; Ernest James Coombe, St. George's Hospital; Cecil Lucas Donne, Middlesex Hospital; Saad El Din Ahmed El Daab, Cairo and St. Bartholomew's Hospital; Armin Frank Fuoss, Birmingham University; Lawrence Gill, Guy's Hospital; Sydney Limbery Higgs, Cambridge University and St. Bartholomew's Hospital; Joseph Christopher Campbell Howe, Guy's Hospital; Leslie Cliford Moore, Liverpool University and St. Thomas's Hospital; Graham Murray-Shore, private study; Sydney Watson Page, Cambridge University and St. Bartholomew's Hospital; Maurice Pearson, Guy's Hospital; Rupert Idris Rhys, University College, Cardiff, and St. Bartholomew's Hospital; Lewis Henry Douglas Thornton, Cambridge University and Middlesex Hospital; William Stephen Tunbridge, Oxford University and St. Bartholomew's Hospital; Herman Crowther Viehoff, Liverpool University; William Harold White, St. Thomas's Hospital; Catherine Mabel Williams, London School of Medicine for Women; and Vyvian Deane Wyborn, Charing Cross Hospital.

LETTERKENNY MEDICAL OFFICERSHIP.—Our Belfast correspondent writes: Nowhere but in Ireland could such extraordinary topsy-turvy situations arise as have occurred in relation to the medical officership of Letterkenny Dispensary. At a meeting of the board of guardians, held on Jan. 12th, the political party which was previously in the minority found themselves by mere chance in the majority, with the result that the account of Mr. T. Patterson for £5 8s. for acting as locum-tenant for Dr. J. P. McGinley during the latter's absence at the winter assizes was refused, on the grounds that the Local Government Board had not sanctioned the appointment of either of these medical men. Dr. W. N. Walker's bill, for acting as temporary medical officer (he having been recognised by the Local Government Board) was ordered to be paid, the amount being £79 9s. 10d. Finally the items on the pay-sheet for Dr. McGinley were refused to be sanctioned for payment, on the grounds that his appointment had not been sanctioned by the Local Government Board.

ROYAL INSTITUTE OF PUBLIC HEALTH.—A course of lectures is being delivered under the auspices of this Institute dealing with public health problems under war and after the war conditions. The lectures are delivered on the Wednesdays of January, February, and March at the lecture room of the Institute, 37, Russell-square, London, at 4 P.M., and the delivery of the first two by Miss Janet Lane-Claypon, M.D., and Mrs. Scharlieb, M.D., respectively, have already been announced. The lectures still to come are as follows:—Jan. 31st: Dr. Chas. John Macalister on the Prevention and Arrest of Venereal Disease in Men. Feb. 7th: Lady Barrett, M.D., on the Rôle of the Midwife and the Protection of Motherhood. Feb. 14th: Lieutenant-Colonel S. A. M. Copeman, M.D., F.R.S., on the Prevention and Arrest of Infectious Disease in War-time. Feb. 21st: Dr. T. D. Lister on the Tuberculosis Problem in War-time. Feb. 28th: Dr. W. G. Savage on the Protection of the Milk-supply. March 7th: Professor F. G. Hopkins, F.R.S., on the Selection and Preparation of Foods in War-time. March 14th: Dr. E. L. Collis on the Protection of the Health of Munition Workers. March 21st: Professor Sir Thomas Oliver, F.R.S., on the Hygiene of Occupation in War-time. March 28th: Lieutenant-Colonel Sir A. Pearce

Gould, K.C.V.O., on Personal Habits in Relation to Public Health in Time of War. Prominent workers in connexion with the various different subjects have promised to be present at the lectures and to take part in any discussion which arises.

THE gross takings of a disorderly house in Torrington-square were stated, at a prosecution at Bow-street police-court this week, to be at the rate of over £5000 a year.

THE Home Secretary has extended until Feb. 28th the time during which unregistered dentists may purchase preparations containing not more than 1 per cent. of cocaine.

THE National Institute of Mothercraft has received an anonymous donation of £5000 to equip and maintain its ante-natal clinic.

## Appointments.

*Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

DOUBLEDAY, F. N., L.R.C.P., M.R.C.S., L.D.S. Eng., has been appointed Dental Surgeon to King George Military Hospital.

ROBERTS, A., M.D. St. And., Certifying Surgeon under the Factory and Workshop Acts for the Harrogate District of the County of Yorks. West Riding.

Boss, B. H., M.R.C.S., L.R.C.P. Lond., to be Certifying Surgeon under the Factory and Workshop Acts for the City of London.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.*

BIRKENHEAD UNION INFIRMARY.—Junior Female Resident Assistant Medical Officer. Salary at the rate of £250 per annum, with board, &c.

BIRMINGHAM CITY.—Female Doctor for Infant Welfare Work. Salary £350 per annum.

BIRMINGHAM CITY EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.

BOLTON INFIRMARY AND DISPENSARY.—Female Second House Surgeon. Also Female Third House Surgeon. Salaries £200 and £180 per annum, respectively, with board, &c.

BRADFORD ROYAL INFIRMARY.—Medical Officer in Charge of Out-patients. Salary at rate of £250 per annum. Also Female Medical Officer for Out-patients. Salary £125 per annum.

BRISTOL GENERAL HOSPITAL.—House Surgeon for six months. Salary at rate of £175 per annum, with board, &c.

CAMBRIDGE, ADDENBROOKES HOSPITAL.—Honorary Assistant Surgeon in Out-patients' Department.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—Second House Surgeon. Salary £150 per annum, with board, &c.

COVENTRY EDUCATION COMMITTEE.—Temporary Assistant School Officer. Salary £350 per annum.

DUMFRIES, Crichton Royal.—Temporary Pathologist and Clinical Pathologist, unmarried. Salary £300 per annum, with board, &c.

GRIMSBY AND DISTRICT HOSPITAL.—House Surgeon. Salary £5 5s. per week, with board, &c.

HARROGATE INFIRMARY.—Resident House Surgeon.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.

—House Physician for six months. Salary 30 guineas.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeons, Assistant Casualty Medical Officer, and House Physician, unmarried. Salary at rate of £60 per annum each, with board, &c.

KENSINGTON BOARD OF GUARDIANS WORKHOUSE AND INFIRMARY.—Second Assistant Resident Medical Officer. Salary £160 per annum, with board, &c.

LEAMINGTON SPA, WARNEFORD GENERAL HOSPITAL.—Junior Resident Medical Officer. Salary £150 per annum, with board, &c.

LEEDS GENERAL INFIRMARY.—Resident Aural Officer. Salary £100 per annum, with board, &c. Also Ophthalmic House Surgeon. Salary £50 per annum, with board, &c.

LEICESTER CORPORATION.—Female Second Resident Medical Officer for Isolation Hospital and Sanatorium, Groby-road. Salary at rate of £250 per annum, with board, &c.

LISBURN, WALLASLEY, VICTORIA CENTRAL HOSPITAL.—House Surgeon. Salary £250 per annum.

NEWCASTLE-UPON-TYNE, ROYAL VICTORIA INFIRMARY.—Female Assistant in Venereal Diseases Department.

ORTHUMBERLAND CHILDREN'S CONSUMPTIVE SANATORIUM, Stannington.—Female Resident Medical Officer. Salary £200 per annum, with board, &c.

NOTTINGHAM AND MIDLAND EYE INFIRMARY.—Female House Surgeon. Salary £120 per annum.

PLAISTOW HOSPITAL FOR INFECTIOUS DISEASES, London, E.—Temporary Resident Medical Officer. Salary at rate of £250 per annum, and all found.

QUEEN MARY'S HOSPITAL FOR THE EAST-END, Stratford.—House Surgeon.

ROCHESTER, ST. BARTHOLOMEW'S HOSPITAL.—Clinical Assistant. Salary at rate of £110 per annum, with board, &c.

ST. GEORGE'S HOSPITAL, Hyde Park Corner, S.W.—Surgical Registrar. Salary £200 per annum, with board, &c.

ST. MARK'S HOSPITAL, City-road, E.C.—House Surgeon.

ST. PANCRAS DISPENSARY, 39, Oakley-square, W.—Resident Medical Officer. Salary £150 per annum, with residence, &c.

SCOTLAND, NAVAL AUXILIARY HOSPITAL.—Assistant Surgeon and Medical Officer. Salary £1 per day, with board, &c.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £120 per annum, with board, &c.

SOUTHAMPTON PARISH INFIRMARY, Shirley Warren.—Resident Assistant Medical Officer. Salary £250 per annum, with board, &c.

STAFFORDSHIRE, WOLVERHAMPTON, AND DUDLEY JOINT COMMITTEE FOR TUBERCULOSIS, MOXLEY SANATORIUM, near Wednesbury, Staffs.—Resident Medical Officer. Salary £350 per annum, with board, &c.

SUNDERLAND ROYAL INFIRMARY.—Female House Surgeon. Salary £150 per annum, with board, &c.

UNIVERSITY OF LONDON.—External Examiners.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Surgeon for six months. Salary at rate of £200 per annum, with board, &c.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Resident Surgical Dresser.

WORCESTER, CITY OF.—Female Temporary Assistant Medical Officer. Salary £350 per annum.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Amlwch, Anglesey.

## Births, Marriages, and Deaths.

### BIRTHS.

MAXWELL.—On Jan. 3rd, at Prince's-gate, W., the wife of Lieutenant H. B. Maxwell, R.A.M.C., of a son.

ROBIN.—On Jan. 2nd, at Sidmouth, the wife of Arthur Robin, M.D., of a son.

WILSON.—On Jan. 10th, at Harley-street, W., the wife of Dr. S. A. Kinner Wilson, of a son.

YOUNG.—On Jan. 10th, at Inverness-gardens, Kensington, the wife of Captain (Temporary) F. P. Young, R.A.M.C., of a daughter.

### MARRIAGES.

BURD—WALKER.—On Jan. 8th, at All Saints, Bournemouth E., Lycett Burd, M. Cantab., to Elizabeth, daughter of the late E. V. Walker, Dewsbury.

COLLEDGE—BRACKENBURY.—On Jan. 15th, at St. Stephen's Church, Hampstead, Lionel Colledge, Captain, R.A.M.C., to Margaret Mary, eldest daughter of Admiral J. W. Brackenbury, C.B., C.M.G., and Mrs. Brackenbury, of Belgrave-square, Hampstead.

HART—PEARSON.—On Jan. 9th, at St. Barnabas Church, Addison-road, W., William Malloch Hart, M.C., C.A.M.C., to Mary Dorothy, only daughter of E. W. Pearson, of the Inner Temple, Barrister-at-Law, and Mrs. Pearson.

HOFFMAN—WENDEN.—On Jan. 6th, at Dursley Parish Church, Geoffrey Arthur Hoffman, M.B., to Mary, eldest daughter of Major Wenden, V.D., "The Chantry," Dursley.

LESLIE—LUPTON.—On Jan. 13th, at Essex Church, Kensington, Captain William Leslie, R.A.M.C., to Mary Beatrice, third daughter of Henry Lupton, of Torquay.

WEAVER—SIPPE.—On Jan. 9th, at St. Paul's, Portman-square, L. Bargrave Weaver, L.D.S. Eng., to Esther, youngest daughter of Mr. and Mrs. Charles H. Sippe, of Beckenham, Kent.

### DEATHS.

BROWN (Chester-le-Street).—At 4, Red Rose-terrace, on the 9th inst., William James, son of the late James Brown, of Dublin, and dearly beloved husband of Frances Ann Brown, daughter of the late Dr. Paul Maude Edger, of Hartlepool. Born at Dublin Feb. 21st, 1849. Educated at Professor Graham Bell's School, Dublin, Bishop Stortford Collegiate School, Herts., and Institution Berchoud Asnières, near Paris; B.A., M.B. Dublin; L.R.C.S.I.; L. Med.; L.M.I.D., T.C.D., and L.M., Rotunda Hospital, Dublin; Certifying Factory Surgeon; late Surgeon-Captain 4th D. I. I.; late Surgeon to the Chester-le-Street Ironworks; Examiner for Army and Militia recruits; late Medical Officer to Newcastle-on-Tyne Borough Lunatic Asylum; late House Surgeon and Secretary to the Harlepool Hospital; contributor to the *British Medical Journal*, *Lancet*, and *Journal of Medical Science*; Past Master of the Earl of Durham Lodge of Freemasons, P.P.G.P. Grand Provincial Lodge, Durham, and a member of the Royal Arch Chapter of Concord.

FLOWER.—On Jan. 14th, at Boscombe, Hants. Frederick Isaac Flower, M.R.C.S., L.R.C.P., formerly of Warminster, Wilts., in his 75th year.

GOWANS.—On Jan. 15th, at Broughty Ferry, Dundee, James Gowans, M.B., C.M.

HAMILL.—On Jan. 7th, at Clowes House, Higher Broughton, Manchester. Dr. J. Wilson Hamill.

MORRIS.—On Jan. 8th, at Parkside, Feltham, Middlesex, Colin Dwight Morris, M.R.C.S., L.R.C.P., L.S.A., aged 58.

MUNRO SMITH.—On Jan. 13th, at Apesley-road, Clifton, Bristol. George Munro Smith, M.D., L.R.C.P. Lond., M.R.C.S., Hon. and Consulting Surgeon to the Bristol Royal Infirmary, late Lt.-Colonel R.A.M.C. (T.).

SANSOM.—On Jan. 9th, at West End-lane, West Hampstead, Harry Arthur Sansom, M.D., aged 53.

WELCH.—On Jan. 11th, at Blenheim-gardens, Cricklewood, John Welch, M.D., aged 92.

N.B.—1/- fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

**THE EARLY TREATMENT OF GUNSHOT WOUNDS.**  
 In the *Quarterly Review* for October, 1916, Dr. Charles Singer published an interesting article under this title, accompanied by four pages of illustrations depicting (1) "An instrument for straightening a stiff and contracted joint"; (2) "Cauterising a wound" (both from Gersdorff, 1517); (3) "Ambrose Paré, aged 75"; and (4) (a) "The stork-beak wound dilator," (b) the "Alphonsinum" (a sort of "porte-crayon" bullet extractor, named after Alfonso Ferri, 1515-95), and (c) Paré's artery forceps. Eight books on the history of medicine are chiefly referred to—viz.: Brunschwig 1497, Giovanni de Vigo 1514, Hans von Gersdorff 1517, Conrad Gesner 1555, "Paré's Works" by J. F. Malgaigne 1840, Theodor Billroth 1859; "Ambrose Paré and his Times," by Stephen Paget, 1897; and the "History of Surgery," by E. J. Gurit, 1898. In respect of the invention of gunpowder, Dr. Singer refers to the "semi-mythical German monk, Berthold the Black, about the year 1313." This is our old school hero, "Schwarz" anglicised, whose name was really, according to some authorities, "Konstantin Anklitzel," though most of us will always call him "Schwarz." Among other notables who cross Dr. Singer's stage may be mentioned the fourteenth-century Czech general, John Ziska, who became blind without resigning his command, and Matthias Corvinus (d. 1490), King of Hungary, who was a son of "Hunjadi Janos," whose name is familiar to many, having been borrowed for an aperient water years ago. Bartolomeo Maggi (d. 1552), a Bolognese military surgeon, and Leonardo Botallo, a Piedmontese anatomist (fl. circa 1550), and their support of some of Paré's doctrines on gunshot wounds are referred to, as well as Laurent Joubert (1529-83), Paré's most influential supporter, and Felix Wirtz (1514-74) of Basel, a Swiss and friend of Conrad Gesner. Wirtz was much praised by Billroth and other German writers. In conclusion, the level of surgery in England during the sixteenth century is discussed and the names of Thomas Gale (1507-87) and William Clowes the elder (1540-1604) are mentioned, with a quotation from the latter's work published in 1588: "A prooved practise for all young Chirurgions, concerning burnings with Gunpowder, & wounds made with Gunshot, Sword, Halbard, Pike, Launce or such other." Dr. Singer says that Clowes was a master of vituperative controversy. He writes very hardly of the "wicked brood of beastly abusers of Phisicke and Chirurgie, daylie more and more increasing to the utter undoing of many." We notice a double reference to "Heinrich von Pfolsprundt." Dr. Garrison in his "History of Medicine" spells this "Pfolspeundt." The date of Matthias Corvinus's birth is given in reference books as 1443 and not 1450. Maggi's year of birth is queried by Dr. Singer as "1477." Dr. Garrison states 1516; and the year of Ambrose Paré's birth, which Dr. Singer gives as 1510, has been given in many French and English books as 1517; but here there is some confusion probably.

### VITAL STATISTICS OF GIBRALTAR.

THE Gibraltar Blue-book for 1915 gives the estimated civil population of the city and harbour as 8707 males and 9236 females—total 17,943, showing a decrease of 1643 as compared with the census of 1911. The births registered during the year numbered 368 and the deaths 330. The total number of patients treated in the Colonial Hospital was 784 and there were 59 deaths. Of 291 who underwent surgical operations, 7, or approximately 2 per cent., died. The number of out-patients treated was 7754. In the small-pox hospital 24 patients were treated, of whom two died. At the Tuberculosis Dispensary, under the management of the Sanitary Commissioners, the monthly attendance of patients for inspection and treatment during the year averaged 55.5. In the Tuberculosis Home, under the same management, 23 adults and 36 children were accommodated at different periods of the year. The number of patients visited at their homes by the medical officer of health averaged 30 each week; 11,396 lb. of beef and 22,905 pints of milk were distributed to patients during the year. There were 6 deaths in the Home from advanced tuberculosis. The daily average number of patients in the lunatic asylum was 34 (22 males and 12 females); there were three deaths. The mean maximum temperature for the year was 69.2° and the mean minimum 57.2°. The rainfall was 53.2 inches, as against 36.75 in the previous year.

R.—We have no information on the subject. The scheme has not yet been before the Director of Public Services. We expect the working to be left, as our correspondent suggests, at least as long as the War Office is satisfied.

## Medical Diary for the ensuing Week.

### SOCIETIES.

**ROYAL SOCIETY**, Burlington House, London, W.

**TUESDAY.**—Papers.—Lord Rayleigh O.M.: On the Dynamics of Revolving Fluid.—Hon. R. J. Strutt: Spectroscopic Observations on the Active Modification of Nitrogen. V.—Prof. J. W. Nicholson and Prof. H. Wilson: Magnetic Induction and its Reversal in Spherical Iron Shells (communicated by Prof. J. A. Fleming).—Mr. S. Brodetsky: The Two-dimensional Motion of a Plane Lamina in a Resisting Medium (communicated by Prof. G. C. Bryan).

**ROYAL SOCIETY OF MEDICINE**, 1, Wimpole-street, W.

### MEETINGS OF SECTIONS.

Monday, Jan. 22nd.

**ODONTOLOGY** (Hon. Secretaries—F. M. Smyth, F. N. Doubleday, J. Howard Mummery): at 5.30 P.M.  
Paper:

Dr. A. E. Rowlett: Conductive Anaesthesia of the Mandible.  
N.B.—Members will please note the change of time to 5.30 p.m.

Tuesday, Jan. 23rd.

**MEDICINE**, **PATHOLOGY**, **EPIDEMIOLOGY** { Combined Meeting : at 5 P.M.

### Discussion :

"The Origin, Symptoms, Pathology, Treatment, and Prophylaxis of Toxic Jaundice observed in Munition Workers and Troops." Surgeon-General H. D. Rolleston will take the chair, and the discussion will be opened by Dr. T. M. Legge, H.M. Medical Inspector of Factories.

**PSYCHIATRY** (Hon. Secretaries—Bernard Hart, G. F. Barham): at 4.30 P.M.  
Communication :

Dr. F. Sano: Morphological Investigations upon the Convolutions of Relative Brains in Man.  
N.B.—For the general convenience of members during the war, the Council has decided to hold the meetings of this Section at 4.30 p.m. instead of 8.30 p.m.

Thursday, Jan. 25th.

**BALNEOLOGY AND CLIMATOLOGY** (Hon. Secretaries—Chas. W. Buckley, J. Campbell McClure): at 5.15 P.M.  
Paper:

Dr. A. G. S. Mahomed: Distribution of Deaths from Lightning-stroke in England.

Dr. J. Horne Wilson: Galvanometric Diagnosis and Dielectric Therapy, with Description of Methods used.

(At 7.30 P.M. the members will dine together at Pagans' Restaurant, Great Portland-street, W., and members may bring guests. Members who wish to dine are requested to send their names to Dr. J. Campbell McClure, 59, Harley-street, W.)

**NEUROLOGY** (Hon. Secretaries—H. Campbell Thomson, C. M. Hindle Howell): at 8 P.M.  
A CLINICAL MEETING will be held at King George Hospital, by kind permission of Lieut.-Colonel Cottell, R.A.M.C.

Friday, Jan. 26th.

**STUDY OF DISBANE IN CHILDREN** (Hon. Secretaries—A. S. Blundell Bankart, E. A. Cockayne, C. P. Lapage): at 4.30 P.M.  
Case will be shown.

### Short Paper :

Dr. J. Porter Parkinson: Pneumonia with Hyperpyrexia followed by Heart Block.

**ROYAL SOCIETY OF ARTS**, John-street, Adelphi, W.C.  
Wednesday.—4.30 P.M., Paper:—Mr. W. A. M. Goods: Relief Work in Belgium.

**HUNTERIAN SOCIETY**, at the Royal Society of Medicine, 1, Wimpole-street, W.

Wednesday.—9 P.M., Mr. F. Kidd: Demonstration on Surgical Diseases of the Urethra.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**POST-GRADUATE COLLEGE**, West London Hospital, Hammersmith-road, W.

**MONDAY.**—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

**TUESDAY.**—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

**WEDNESDAY.**—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

**THURSDAY.**—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

**FRIDAY.**—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

**SATURDAY.**—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE**, Princes of Wales's General Hospital, Tottenham, N.

**MONDAY.**—Clinics:—10.30 A.M., Surgeon Out-patients (Mr. R. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham); Gynaecological Out-patients (Dr. Bunting). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

**TUESDAY.**—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Arnold); Surgical Out-patients

(Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Mayton). Radiography (Dr. Metcalfe). 3.30 p.m., Medical In-patients (Dr. A. J. Whiting).

**WEDNESDAY.**—Clinics:—2.30 p.m., Throat Operations (Mr. C. H. Mayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 p.m., Eye Operations (Mr. R. P. Brooks).

**THURSDAY.**—2.30 p.m., Gynaecological Operations (Dr. A. H. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 p.m., Medical In-patients (Dr. R. M. Leslie).

**FRIDAY.**—2.30 p.m., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. H. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN,** 49, Leicester-square, W.C.

**TUESDAY.**—4 p.m., Dr. C. Kempster: X Rays. Rodent Ulcer and Malignant Diseases.

**THURSDAY.**—6 p.m., Chesterfield Lecture:—Dr. M. Dockrell: Vesicular and Bullous Diseases and their Treatment.

**ROYAL INSTITUTE OF PUBLIC HEALTH,** Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

**WEDNESDAY.**—4 p.m., Lecture II.:—Dr. Mary Scharles: The Prevention and Arrest of Venereal Disease in Women. Dr. G. W. Saleby, Dr. Jane H. Walker, and Dr. Helen M. Wilson have promised to take part in the discussion.

**ROYAL INSTITUTION OF GREAT BRITAIN,** Albemarle-street, Piccadilly, W.

**TUESDAY.**—3 p.m., Prof. C. S. Sherrington: The Old Brain and the New Brain, and their Meaning. (Lecture II.)

### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Office: 423, STRAND, LONDON, W.C.

### MANAGER'S NOTICES.

#### VOLUMES AND CASES.

VOLUMES for the second half of the year 1916 will be ready shortly. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half-year's numbers (inland edition) are now ready. Cloth, gilt lettered, price 2s., by post 2s. 4d.

To be obtained on application to the Manager, accompanied by remittance.

#### ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

#### TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

#### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Office.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world.

### METEOROLOGICAL READINGS.

(Taken daily at 3.30 a.m. by Steward's Instruments.)

THE LANCET Office, Jan. 17th, 1917.

Date.	Sun-fall.	Star Radio in Vizor.	Maxi-mum Temp. Shade.	Min. Temp.	Wet Bulb.	Dry Bulb.	Remarks.

## An Analysis

OF

### RECENT CASES OF TETANUS IN THE BRITISH EXPEDITIONARY FORCE. WITH SPECIAL REFERENCE TO THEIR TREATMENT BY ANTITOXIN.

By SIR WILLIAM B. LEISHMAN, C.B., F.R.S.,  
F.R.C.P., LL.D., K.H.P.,  
COLONEL, ARMY MEDICAL SERVICE;  
AND  
A. B. SMALLMAN, D.S.O., M.D., D.P.H.,  
MAJOR, ROYAL ARMY MEDICAL CORPS.

SOME of the medical problems of the war, though of much scientific interest, are less urgent than others, and may well await the leisureed study which will without doubt be given to them after its conclusion, but others which are more urgent appear to call for at least a partial attempt to reach agreement before the campaign grows older. Prominent among these appears to us the subject of the specific treatment of tetanus, upon which there exist wide differences of view, both as to the usefulness of antitoxin at all and, admitting its value, as to the system of its employment which may be expected to yield the best results.

Earlier in the war information with regard to tetanus in the Army in France was collected by one of us (W. B. L.) and summarised in one of the sections of the official "Memorandum on the Treatment of Injuries in War," which was published in July, 1915, and circulated to all medical officers. Further experience of the treatment of the disease has accumulated since then, but much of it relates to comparatively small groups of cases observed in a single hospital, and cases fortunately have on the whole been so few that a number of general hospitals may not have seen one for months. Recently a Tetanus Committee appointed by the War Office, under the chairmanship of Surgeon-General Sir David Bruce, has collected a large amount of most useful information in connexion with the cases which have been treated in home hospitals, and have published their results and recommendations, partly in the form of circular memoranda and partly in an article in *THE LANCET* of Dec. 2nd, 1916, by Sir David Bruce. We have remodelled some of our tables upon those adopted by Sir David Bruce, so that they may be read as complementary one to the other, and may in this way serve to bring into greater relief the points in which the experiences of home hospitals are in contrast or in accord with those acquired in the Expeditionary Force.

Early last summer it was felt that we had reason to anticipate the occurrence of a certain amount of tetanus among the large number of wounded to be expected during the coming offensive on the Somme. Although since the days of the battle of the Aisne strict orders exist that every wounded man should receive a prophylactic injection of tetanus antitoxin, and it is exceedingly rare that this is for any reason omitted, still it is well recognised that this cannot confer absolute protection. The severe character of many of the wounds is only too familiar to us all, and the heavy coating of foul mud, with which skin and uniform are almost always plastered, renders it certain that very large doses of anaerobic and other bacteria are at times driven deeply into the devitalised tissues.

Arrangements were therefore organised for the collection of detailed information in respect of every case of tetanus occurring in France, a number of questions being asked on a form which had to be completed and sent to headquarters on the termination or final disposal of the case. The information given on the sheets was then transferred to cards, which facilitated the analysis of the various points under inquiry. On the whole, the required details have been very accurately recorded, but it will be realised that at times of heavy pressure in field ambulances and casualty clearing stations it is often difficult or impossible to obtain and record the full details on certain points. These must later be ascertained; if at all, from a man who may be too ill to

cross-examine or who may own the notoriously inaccurate memory of at least the old soldier for such points as dates and hours.

We have classed the cases simply into those who died and those who recovered. At first we divided them into three classes: (1) Those whose deaths were attributed solely to tetanus; (2) those whose deaths were in larger part attributable to complications, such as severe sepsis, gas gangrene, secondary haemorrhage, &c.; and (3) the recoveries. It was found, however, that the difficulties of deciding in which subdivision to place the fatal cases were too great and too uncertain. A simple distribution into the two classes has the disadvantage that the total deaths from tetanus inevitably include a number of cases in which the condition of the wound, the exhaustion of the patient, or some complication were in themselves quite sufficient to account for death. They also comprise cases in which it was definitely stated that all symptoms of tetanus had disappeared before death. Such cases naturally weigh the scales against whatever system of treatment had been employed for the tetanic symptoms. On the other hand, however, the symptoms recorded in some cases have been so slight as to suggest the possibility that they might not have been due to tetanus at all; and, if this were so, such cases would form a counter-weight to those whose death was not due to tetanus.

The present analysis is based upon 160 cases which occurred in hospitals in France between July 1st and Oct. 31st, 1916. Of these cases 118 died and 42 recovered, a case-mortality of 73·7 per cent. This mortality may be contrasted with that of the group of cases, already alluded to, examined by one of us in the spring of 1915. In that series, among 179 cases there were 140 deaths, a case-mortality of 78·2 per cent. This, as far as it goes, does not disclose any considerable degree of improvement in the treatment employed. Both series show a heavier death-rate than that which has been recorded for the cases treated in home hospitals where, during the first year, out of 231 cases analysed by Sir David Bruce, there was a case-mortality of 57·7 per cent., and, for the second year, up to July 31st, 1916, out of 195 cases a mortality of 49·2 per cent.

These four series show a slight improvement in case-mortality on each side of the Channel, but also make it clear that cases are more fatal in France by about 25 per cent. The causes for the latter fact are so obvious as to need no labouring. The most desperate wounds, which it would be dangerous to move, and which are therefore detained in clearing stations or base hospitals, are just those which are most likely to develop tetanus, and, further, the complications of severe sepsis, gas gangrene, &c., which must be more in evidence closer to the line than in home hospitals, more frequently play a large part in determining a fatal issue in cases of tetanus.

#### INCIDENCE.

It is not permissible at the present moment to give any information upon the actual incidence of the disease among the wounded, or to contrast one period of the war with another from that point of view, but there can be no harm in mentioning an impression, which we have gathered from the figures in question, that the highest incidence will eventually be found to be associated with periods during which heavy fighting took place in wet weather. This, after all, might have been anticipated, as it is obvious that, under such conditions, the change from dust to mud will mean a heavier bacterial inoculation of the wound.

An analysis of the influence of the prophylactic dose of antitoxin upon the general incidence of the disease must, for the same reason, be passed over; but this is, fortunately, a procedure which is so fully accepted, not only by ourselves but by our Allies and our enemies, that it stands in little need of further statistical support. Were it not for the universal acceptance of the protective value of this dose we feel sure that any analysis of the subject would have had to deal not with a few hundred cases but with many thousands.

#### THE INFLUENCE OF THE SEVERITY AND CONDITION OF THE WOUNDED.

In connexion with each case information was asked for on a number of specific points, and among these were queries as to the existence of severe sepsis or gas-infection of the tissues. Details were also asked to the nature and severity of the wound, itself and whether it was single or multiple. Table I. shows the frequency with which these factors were

encountered in each group—i.e., among 113 fatal cases and 42 recovered cases. (It will be understood that, where the total number of cases shown in any table does not reach 160, the required information had not been obtained in every case.)

The table shows, as might be expected, a considerably higher percentage occurrence of these conditions among the fatal cases. The most striking contrast is that shown in the

TABLE I.—*Condition of Wounds as Regards Sepsis, Presence of Gas Gangrene, &c.*

—	Severe sepsis.	Gas gangrene.	Extensive or severe wound.	Multiple wounds.
Fatal—113 cases ... {	88 (78%)	61 (54%)	98 (87%)	62 (55%)
Recovered—42 cases {	24 (57%)	5 (12%)	26 (61%)	18 (43%)

much greater frequency of gas gangrene as a complicating factor in the cases which terminated fatally, no less than 54 per cent. of these cases having been noted as suffering from this grave complication. Its dangerous nature is but too well known, and its frequency among these cases is, to our minds, one of the chief causes of the relatively higher death-rate from tetanus in France as compared with the experience at home.

Another point in connexion with the factors complicating a judgment on the results of treatment appears to be the site of the wound, independently of the influence of sepsis or gangrene. It has been noted by us that a fatal issue is more common when the body, as distinguished from the limbs, has been wounded. Thus, as will be seen in Table II., out of 115 fatal cases, 61, or 53 per cent., were cases in which the

TABLE II.—*The Position of the Wounds in Reference to the Mortality.*

—	Body.	Limbs.
Fatal: 115 cases ... ... ... ...	61 (53%)	54 (47%)
Recovered: 42 cases ... ... ... ...	18 (43%)	24 (57%)

Note.—When wounds occurred both on the body and the limbs the case is counted only under the heading "body."

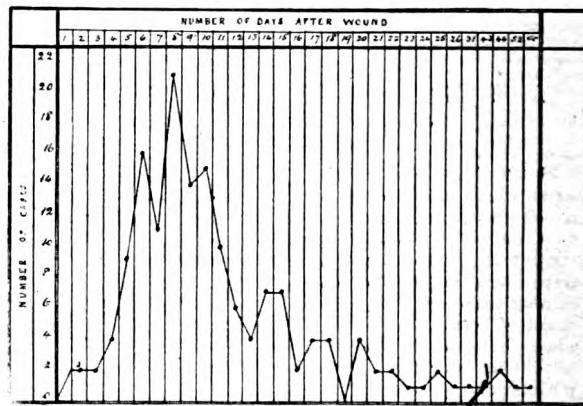

wound or some of the wounds involved the head or trunk, the balance of 54 cases, or 47 per cent., being wounds of a limb or limbs. On the other hand, of 42 cases which recovered 18, or 43 per cent., were wounds of the body, the remaining 24 recoveries, 57 per cent. of the whole, having received wounds of the legs or arms only. The difference in these figures, though not very marked, appears suggestive, and the heavier mortality of the body cases may not improbably be related to the shorter distance which the toxin has to travel in order to reach the spinal cord and the nervous centres.

#### THE INCUBATION PERIOD.

The interval which elapsed between the wound and the first evidences of tetanus was recorded in 157 cases and a curve has been constructed, similar to that in Sir David Bruce's papers, that the experience in France may be contrasted with that at home. The average incubation period of all the cases was 12·03 days. Of the fatal cases, 115 in number, the average period was 10·7 days, and of the 42 recoveries it was 14·4 days. This confirms once again the general experience that the shorter the interval between the wound and the attack the poorer the chance of the patient. At the same time, this difference is less marked than might have been expected, being only a fraction above three days, and it corresponds closely to the figures reported by one of us earlier in the war, where the difference was even smaller, 2·74 days. Comparing our curve of the incubation periods with that of the home cases they appear very similar, except that the peak of the curve in France is reached at an earlier day than in England, the eighth as contrasted with the eleventh. This is only what might have been anticipated as a larger proportion of the early and the acute cases fall to us. The shortest incubation period mentioned—two days—occurred in two instances, but in one of these there was an element of doubt as to the exact day of wounding. The other was a slight case which recovered, the presumed source of infection having been a small cut on the index

finger. On the other hand, cases of latent or delayed tetanus are naturally more common in home hospitals, the two in our list with the longest recorded intervals after wounding being, respectively, 52 days and 90 days. Each of these was fatal; the latter was presumed to have originated from an abrasion of the elbow, and in the case of the former an operation had been performed 11 days before the onset of the symptoms of tetanus.

As regards this interesting subject of delayed tetanus, in which it is to be presumed that spores remain undestroyed in the tissues till they are in some way stimulated to germination, we have 13 cases in our series in which the

Curve of the incubation period.

disease did not make its appearance until 21 days or more had elapsed. This may perhaps be assumed to be the limit of the normal incubation period, although the phrase is an awkward one to employ in the case of a bacterial disease in which the germs are introduced as spores which, theoretically, may lie dormant but living in the tissues for an indefinite time. Of these 13 cases, 8 died and 5 recovered. The figures are small, but the recovery rate in this group compares favourably with that of the whole series. The average incubation period of the 8 fatal cases was 36·3 days and that of the 5 recovered cases 29·4 days.

#### INFLUENCE OF OPERATION BEFORE THE ONSET OF TETANUS.

Table III. shows a list of the 34 cases in which operative interference of a grave nature had been resorted to prior to the development of the first symptoms of tetanus. Of these 34 cases 26, or 76·5 per cent., died, while 8 recovered, a recovery rate of 23·5 per cent. In 4 cases the onset of the tetanus occurred on the day following the operation and in another 4 cases on the second day after operation. In three instances the initial prophylactic subcutaneous dose had been repeated, in two of them 500 units being given a week after the first one. The third case received a second 500 units 4 days after the first and 1500 units 11 days later, on the day of the operation. Of these 3 cases 2 died and 1 recovered, but in the two fatal cases death was not considered as being primarily due to tetanus. The case which had received the three prophylactic doses died, but death was considered to have been due to sepsis and inanition; there had been no convulsions for 6 days before death. Out of 9 cases where death occurred within 3 days of operation 7 were amputation cases; in the 2 remaining ones the wounds and the operations involved the thorax. On the other hand, out of 8 recoveries 3 only were amputations, and only in one case was the thorax involved.

It may be noted that 34 out of our 160 cases fall to be described in this category, as contrasted with the 15 cases out of a total of 195 shown on Sir David Bruce's last communication. This disproportion is readily understandable as these grave operations are naturally demanded more often, and at an earlier moment, in France than in the case of wounded men whose condition was considered such that they could bear the journey to England without undue risk.

#### INFLUENCE OF OPERATION AFTER THE ONSET OF TETANUS.

The practice of operating after tetanus has declared itself appears to be dying out in France. Table IV. deals with only 9 such cases, and no case of this nature has been reported to us since the end of September. Of the 9 cases 7 died and

2 recovered, a case mortality of 77·7 per cent. Of the 2 cases which were most quickly fatal—viz., 1 day and 1½ days—it may again be remarked that each was a body wound; the operations apparently involved much manipulation and may thus have opened up fresh channels

for the absorption of toxin by a short route. Among the 7 deaths there were 3 amputations, but, on the other hand, both of the recoveries were also amputation cases.

The figures dealt with in these two tables III. and IV. are too small to throw fresh light on a side of the problem which has been much discussed, but we have no doubt as to the wisdom of giving a sufficient prophylactic dose a short

time before a contemplated operation, and we believe that it is generally agreed to be wise to refrain from any avoidable disturbance of the wound, or anything in the nature of a severe operation, once tetanus has declared itself, at least

TABLE IV.—Operative Interference after Appearance of Tetanus.

until there is some sign of abatement of the symptoms and until a sufficient amount of antitoxin has been administered. The latter question will be mentioned again below.

#### THE PROPHYLACTIC USE OF TETANUS ANTITOXIN.

Although, as has been said, the influence of this upon the general incidence of tetanus in the wounded must be left on one side, there remain some points in connexion with it which are of interest and may be discussed without indiscretion.

It is, of course, well known that the earlier the preventive dose is given after the receipt of the wound the more likely is it to be of use. At the same time there is little positive information as to the effects of delay. An effort was therefore made to obtain precise details as to the number of hours which had elapsed between wound and injection. This was obtained in a considerable proportion of the 160 cases—viz., 66. It would have been easy to group for analysis a still larger number than this if one had been content to include cases in which the replies gave one a reasonable certainty that the dose had been given within 24 hours, but only those have been accepted in which a definite statement was forthcoming as to the fact of inoculation, the dosage, and the number of hours after the wound at which the dose was given.

Of the 43 cases which received within 24 hours a preventive dose of 500 or more units—less is never given—62·7 per cent. were fatal and 37·2 recovered. On the other hand, of 23 cases in which the giving of the antitoxin was, for one reason or another, delayed beyond 24 hours, 86·9 per cent. died and only 13 per cent. recovered. These figures are given for what they are worth, and it should be borne in mind that delay in giving the preventive inoculation is almost always caused by the impossibility of removing the wounded man from the place where he was hit till military conditions permitted. Such cases are therefore specially liable to gangrene and to the more severe forms of septic trouble.

These 66 cases are further analysed in Table V. to see whether there was any noticeable correlation between the time of administration of the preventive dose, the average size of this dose and the length of the incubation period. The chief points which emerged from this were that the average incubation period of the recovery cases who got their preventive dose within 24 hours is longer than that of the other classes, and that of those whose dose was delayed, and who yet recovered, the average size of the dose given was large—viz., 915 units.

No prophylactic dose was given in 15 of the cases, and 9 of these died—i.e., 60 per cent. It is to be noted, however, that of the 6 who recovered 5 were instances of men whose injuries, being of the nature of scratches or abrasions, were so slight that they did not report sick, and hence received no dose of serum. Others of those who received

no serum were of that unlucky class who have only been picked up some days after their injury, having lain unfound in some shell-hole or perhaps in such a portion of "No man's

TABLE V.—Correlation between the Amount of Prophylactic Dose given, the Time of Administration, and the Incubation Period.\*

land" as made it impossible to reach them. Their condition on rescue has sometimes been so critical that the medical officer did not consider it wise to give an inoculation.

#### THE THERAPEUTIC USE OF TETANUS ANTITOXIN.

The "questionnaire" completed in all cases of tetanus was principally designed to obtain accurate information upon the details of antitoxin administration, the number, size, and route of introduction, and the dates of each dose being asked. This information has been given in every case and has formed the subject of close study from as many different points of view as possible. Our thanks are due to the officers who furnished us with these details, collected often under conditions of great stress. Our object, it need hardly be said, was to search the collected results for any indications for or against a particular system of dosage or a particular channel, or combination of channels, of administration of the antitoxin.

Of the 160 cases, all but three, each of them fatal, were treated with antitoxin, so the tables now to be discussed deal with 157 cases.

The number of possible variations in the treatment adopted, as well as the various complications already alluded to, make it a very difficult matter to arrive at clear-cut answers to any given question, and had there been more general agreement on the usefulness of antitoxin in the treatment of declared tetanus and on the best methods of employing it, we should have preferred to wait till more material had become available for analysis. Still, certain points have rather forced themselves upon our notice in our inquiry into the returns, and we believe them to be of sufficient importance to put on record forthwith.

The paper of Sir David Bruce, dealing as it does with a further 175 cases treated with antitoxin in home hospitals, forms a ready means of multiplying experience on certain points, and we shall frequently avail ourselves of the opportunity thus given of comparing our respective experiences and conclusions.

In examining the results of a certain line of treatment we have, as already said, been content to accept as the criterion of success or failure the survival or death of the patient, leaving out of consideration any statement that death was due in the main to some other cause than tetanus.

Table VI. shows the cases distributed in accordance with the total amount of antitoxin which they had received, being arbitrarily divided for this purpose into eight classes. In each group is shown the number of deaths, the case mortality, and the channels of administration by which the serum had been given. As will be seen, there are no fewer than 15 possible combinations of the four routes which we have had under consideration, and there are instances of each of these combinations having been employed. We have taken no account of a few cases in which antitoxin was said to have been given by the mouth or by the rectum, and there has been no report of its local application to the wound. For the sake of brevity we shall in our tables employ an initial letter to signify the particular route; thus "T" = the intrathecal method, "V" = the intravenous, "S" = the subcutaneous, and "M" = the intramuscular. We shall leave the tables largely to speak for themselves, when they have anything to say, confining our comments to such points as appear to us of significance or as needing further explanation or emphasis.

As regards Table VI., the chief point sought was any broad indication of the effects of the total dosage of anti-

toxin. In studying this point we at one time divided our cases accordingly as they had received a total dosage of less or more than 20,000 units. Although we decided later to abandon this method for the succeeding tables as too complicating, we may return to it here as bringing out the

\* T. = Intrathecal. V. = Intravenous. S. = Subcutaneous.

M. = Intramuscular.

The cases are grouped according to the total dosage given, together with the case mortality. The groups are subdivided to show how many cases fall into each one of the 15 possible combinations.

desired point somewhat more clearly. As will be seen, the first five classes, those in which the total dosage had been below 20,000 units, comprise 116 cases, of whom 91 died, a case mortality of 78·4 per cent. The remaining 41 cases received more than 20,000 units, and of them 24 died, a case mortality of 58·5 per cent. There is therefore a balance of 20 per cent. in the favour of the larger dosage. Turning to a somewhat similar table in connexion with the cases treated in home hospitals, and dividing the 175 cases therein analysed into similar groups, below and above a total dosage of 20,000 units, we find that of 108 cases in the small-dose category, 61 died, a case mortality of 56·4 per cent., while of the 67 cases in the large-dose class only 21 died, a case mortality of 31·3 per cent. The balance here in favour of the larger total dosage is 25 per cent., a difference even more pronounced than in our own series.

Taken together, we think there can be little doubt that they demonstrate the better results obtainable from the higher dosage. We have very closely scrutinised our cases to see what influence certain obviously possible fallacies might have had upon this conclusion. For instance, it is possible that relatively small dosage may have been adopted of necessity because the case was rapidly fatal, either from tetanus or a complication; or, on the other hand, the case may have been so slight that the dosage was originally small and was rapidly abandoned. Such cases undoubtedly occur, but against them may be set, unfortunately, the equally certain fallacy that even in severe and prolonged cases the dosage recorded has, in our view, at least, been altogether inadequate, owing to an obvious disbelief in the value of specific treatment. These, and some other disturbing factors, we think tend to cancel one another and we do not consider that they lessen materially the significance of the figures just quoted.

TABLE VII.—Showing the Total Number of Cases Treated by Serum (with or without Non-specific Treatment), together with the Number of Deaths and the Case Mortality. The Table also shows the Number of Cases treated by any one of the Four Available Routes alone or in Combination with One or More of the other Three Routes.

The next table, VII., sets out the cases treated by antitoxin and it shows for each route or combination of routes by which the serum was given, the number of cases, the deaths,

and the case mortality. The uneven size of the groups, and their very number, make evident the futility of any attempt to form conclusions from a consideration of the degree to which the case-mortalities are above or below the mean rate of the whole 157 cases. A better opportunity is afforded by a consideration of the series of Tables VIII., IX., X., and XI., in which the cases are grouped on a different system. Here we have placed together all cases in which one particular route, whether alone or in combination with others, formed part of the system of treatment, a separate table being devoted to each of the four—"T.", "V.", "S.", and "M.". Each of these will now be briefly considered.

Table VIII. deals with the intrathecal route, employed either alone or combined with others. It was used alone in 25 cases, with a mortality of 84 per cent., and this, with the single exception of the combination "T.V.S.", is, it will be noted, the highest rate shown in the table. Looking to Sir David Bruce's figures we see that "T." was used alone in 7 cases, of which 5 died, a mortality of 71·4 per cent., the highest mortality of any group analysed in his paper. So far this does not impress one favourably. Turning to the use of "T." in combination with others, the only other point we shall call attention to is that in each of the four groups

showing the lowest mortality the intramuscular route has formed a part of the combination. The moral would appear to be that if one employs the thecal route at all it is better to use it in combination than alone. This is even more strikingly illustrated in the home figures, where the relative death-rates are 71·4 per cent. and 46·7 per cent.

Table IX. deals in a similar way with the intravenous route alone or combined. Of 55 cases in the group 44 died, a mortality of 80 per cent., and we have the striking fact brought out that no case treated by this channel alone recovered. In the home figures the mortality in 7 cases treated by "V." alone was 57 per cent., the second highest in the list. Looking again at the results of the various combinations of "V." with other channels, one again notes that the three lowest mortalities are in groups in which "M." appears.

Table X. shows the subcutaneous route alone and in combination with others. Of 87 cases in which this route

was employed the general case mortality was 70 per cent. When used alone, in 27 cases the mortality was considerably lower, 55 per cent., and here the apparent effect of combining this route with others is bad, except in two particular combinations, into each of which "M." again enters. In the home figures the mortality from cases treated by "S." alone was 50 per cent., but there is no information as to the frequency with which it was employed in combination.

Table XI., the last of this group of four, deals in similar fashion with the intramuscular route. Of 32 cases in which it played a part 19 died, a case mortality of 59 per cent., the lowest figure by 11 per cent. of the four tables. The groups are too small here to afford much information, and, so far as the figures go the mortality resulting from its use alone, 75 per cent., contrasts unfavourably with the mean rate of 59 per cent. This group, however, deals with but 4 cases and may be usefully supplemented by the home figures, which show that of 8 cases treated by this method alone only 1 died, a mortality of 12·5 per cent. Combining these 8 cases with our own 4 we have 4 deaths out of 12 cases, a mortality of 33·3 per cent., which is by far the lowest recorded in either series for the results of a single channel antitoxin treatment.

We fully appreciate the many pitfalls into which one may stumble in searching for truth among small figures dealing with cases presenting so many complicating factors; but, so far, our examination of them has given us some strong impressions, all the stronger in that they were by no means anticipated. They appear to us to throw very considerable doubt upon the advisability of employing the intrathecal route, either alone or in combination, and, further, they seem to indicate considerable virtues in connexion with the employment of the subcutaneous and intramuscular channels, particularly the latter. The evidence for and against the intravenous method also leaves one with a feeling of suspicion, particularly in view of the fact that all of the cases treated by this channel alone died.

#### EFFECTS OF THE DOSAGE OF ANTITOXIN EMPLOYED BY THE SEVERAL ROUTES.

It is obvious, however, that, in considering the results of the various combinations of specific treatment dealt with in the last four Tables VIII., IX., X., and XI. there is a factor of importance which is not disclosed by them, but which it is essential to consider. It is not enough to treat all cases as alike that have received serum treatment by the same combination of routes, we must study the amount and frequency of the dosage by each route if we are to reach a fairer judgment of results. This has accordingly been done, and every individual case has been closely studied from this point of view. A table showing the full details of every dose given in the 157 cases was constructed, but as this would be too elaborate to reproduce we have constructed Tables XII., XIII., XIV., and XV., which, while repeating the classification of cases adopted in Tables VIII., IX., X., and XI., show, in addition, the average amount of antitoxin given by each route in each group of cases. This table enables one to grasp more readily the relative importance to attach to each route in any given combination of routes, and to see how this factor of dosage compares in the cases which recovered and those which died.

Table XII. displays all cases in which the intrathecal route played a part. Contrasting the average dose given by the thecal route in the fatal and recovered cases respectively and in each combination, it will be seen that there is no regularity; in some instances more had been given in the recovered cases, in others less. Looking, then, at the venous fraction, here, too, we see no regularity; a larger dosage by the veins seems in some cases to have been beneficial, in others the reverse. But when we consider the remaining fractions, subcutaneous and intramuscular, in each group into which they enter we notice in all cases that the dosage has been higher, usually much higher, in the recovery cases than in the fatal ones. It should be noted, however, that neither in this nor the succeeding three tables of the series do we attempt to draw any inferences from the two cases in class "T.V.S.M." the employment of all four routes appearing to us to render any attempt of this sort futile.

Table XIII. deals in similar fashion with the intravenous route in all combinations. Analysis in this group is difficult, as in no less than four of the combinations we have

either no deaths or no recoveries, as well as the group "V.T.S.M." of which we take no notice. The two groups most suitable for contrast, on account of the number of cases, are "V.T." where the recovered cases show a larger

venous dose and a smaller thecal one than the fatal cases, and Group "V.T.S.M." in which, while the venous average dose is approximately equal in fatal and recovered cases, we are struck by the fact that in three recoveries only half the

thecal dose was given, but three times the subcutaneous dose, as contrasted with the dosage given in the 17 fatal cases.

Table XIV., dealing with the dosage of the subcutaneous route, alone or combined, brings out more clearly than the others the observation that, in all groups in which we are able to make a comparison between the dosage in the recovered and in the fatal cases, a much higher average dose has been given to the cases which lived. This is particularly noticeable in the group treated by the subcutaneous method alone, where the average dose has been 4½ times higher in the cases which recovered, and in the two other fair-sized groups, "S.T." and "S.T.V.", in which the subcutaneous dose was respectively 2½ and 3½ times greater in the recovery cases. In all, this table impresses us with the value of high dosage when the subcutaneous route is employed.

Table XV., the last of this series, shows the average dose of antitoxin employed in all combinations in which the intramuscular route was used. The various groups in this category are, on the whole, too small to extract from them much guidance in this matter of dosage, but it will be seen that in the largest group, "M.T.", dealing with 13 cases, about four times as much antitoxin was given intramuscularly in the recovered cases as in those which died. In the "M.T.S." cases, in which 3 recovered and 1 died, the intramuscular dose was twice as great in those who lived. On the other hand, in the cases treated by intramuscular injections alone, of which 3 out of 4 were fatal, the only case which recovered received less than half of the average dose given to the fatal cases. On the whole, although the figures are small, we get the same impression here as in the instance of the subcutaneous route—that the apparently favourable effect of employing this channel is associated with a proportionally high dosage.

On regarding these four tables from a general point of view, and without attempting to draw from them more than may reasonably be inferred, we find our suspicions of the thecal and venous routes strengthened, and also some further support for the good impression which has been made on us by a consideration of the results of the subcutaneous and intramuscular routes.

The last table which we shall give, Table XVI., was designed in an attempt to visualise and contrast the results obtained by single-route administration of antitoxin with the results of using that particular route in combination with others.

Looking at the intrathecal results, we see that the case mortality is 10 per cent. higher when this route is used

TABLE XVI.—Comparing and Contrasting the Results Obtained by Each Individually, with those Obtained by that Route in Combination with One or More Others.

alone, and also that the total dosage given by the thecal route in the fatal cases was considerably higher in the group in which this channel was employed along with others than when it was employed alone. It was remarked, however, that a considerable proportion of the 21 fatal cases treated by the single-route method were exceptionally severe cases of gunshot injuries. In 9 of them death was

attributed by the reporting officer to causes other than tetanus. Thirteen of them died within 24 hours of the first appearance of tetanic symptoms. Of the recovery cases all were noted as being either slight or localised and none of them reached the stage of trismus.

As regards the intravenous channel, attention has already been directed to the fatal issue in all cases treated by this method alone. The high dosage employed will be remarked, as well as the fact that the average dose given to the recovered cases in whom this channel had been used in combination with others was highest of all. In examining the individual records of the 7 fatal cases treated by the venous route only it was remarked that, although they were all severe wounds, the antitoxin was not persisted in in several, though time allowed for its repetition. In only 2 out of the 7 was the dose above 5000 units.

The subcutaneous route employed alone shows the lowest mortality—viz., 56 per cent. Of the 15 fatal cases 7 were severe wounds, in which death was not attributed directly to the tetanus. The dosage employed in these fatal cases was also remarked upon as being very small, in only one of them was it over 3000 units and most received 1500 units or less. Of the 12 recoveries in the single-route group 6 were either localised or slight, but the dosage only fell below 3000 units in one case, which received 500. The wounds in this group were, on the whole, slight.

Too few cases were treated by the intramuscular route alone to allow of effective contrast with those in which this method was associated with others. Of the 3 fatal cases, 2 were specially severe wounds and the intramuscular dosage was moderate. The recovery case, although severe, was, on the other hand, given 3000 units only. The high average dosage given into the muscles in the 12 recovery cases in the combined group, 18,640 units, is also noteworthy.

#### SUMMARY.

The above analysis of these tables dealing with the therapeutic employment of tetanus antitoxin leaves, we are fully aware, much to be desired, and, at any other time than this, we should have greatly preferred to postpone this article until our material was larger. The importance and urgency of the subject, however, form our justification, and we shall now proceed to summarise the impressions we ourselves have gathered, trusting that we have presented the available facts in such a way that any who wish may do the same.

Our general conclusions would place the alternative channels of administration of the antitoxin in the following order of merit—intramuscular, subcutaneous, intrathecal, and intravenous. Let us consider each separately, emphasising the points of experience or theory which have influenced our judgment. Taking the intravenous route first, as we have placed it last, we are in full agreement with the recommendation of the Tetanus Committee in their revised Memorandum, that this route should not be used; not only does it introduce a risk of anaphylactic shock, from which other methods are practically free, but it appears to us from our records that it has done little, if any, good in treatment. It seems improbable that, even when very large doses are injected into the veins, the antitoxin is likely to be brought to a point at which it is most wanted in a sufficiently concentrated form. Of what is injected only a small fraction can possibly be utilised, and, further, we do not think that the effects of the antiseptic which is mixed with most brands of antitoxin can altogether be neglected when large and repeated doses are injected by this channel.

As to the intrathecal route, we are less inclined to support the recommendation contained in the Memorandum just mentioned when it says: "In a case of tetanus the first thing to do is to give an intrathecal injection of antitoxin." The study of our own cases has not impressed us at all favourably. Sir David Bruce, in his article of Dec. 2nd, considers that the evidence for and against it from his series of cases at home hospitals is not conclusive. We are inclined to go further and consider, from our own tables, and also to some extent from his, that the evidence is pretty strongly against its employment. The theoretical grounds for the adoption of the thecal route are, of course, well known, and depend chiefly on the hope that by bringing antitoxin into more or less close contact with the poisoned nerve cells of the cord we may effect a dissociation between the cell and the molecules of toxin which it has bound to itself. It is known to be very difficult to introduce antitoxin into the cerebro-spinal fluid by means of the blood-stream; hence

the direct path chosen in lumbar puncture. We shall not attempt to analyse the experimental evidence bearing upon this subject, but think it will be agreed that a considerable divergence of opinion still exists as to whether what we aim at, a dissociation of toxin from the poisoned nerve cell, is realisable in practice. The good effect of intrathecal injections of serum in some cases of cerebro-spinal meningitis has really no bearing upon this problem, because, in that instance, we are directly attacking a bacillus which we know to be present in the fluid into which we introduce our anti-serum. Again, in that disease marked benefit often results from the mere evacuation of the turbid fluid which has accumulated under pressure, without even replacing it by an injection of serum.

Apart, however, from doubts as to the soundness of its theoretical basis, the method appears to us to possess some very definite disadvantages and dangers. For example, the dangers of contamination of the needle track, in spite of scrupulous precautions at the time of operation, must be very considerable in certain cases. At all events, definite comments have been made in connexion with some of our cases that thecal injections have been followed by signs of meningeal irritation, and one of us has seen specimens of cords, removed after death from tetanus, in which there was definite evidence of meningitis having followed the lumbar punctures. Again, although Flexner and others have stated that the amount of antiseptic usually added to antitoxin as a preservative is no impediment to its employment by the thecal route, we do not think that repeated injections of carbolic acid, trikresol, &c., can be altogether a negligible consideration in the case of a canal whose limiting membranes are so delicately constituted and their functions so imperfectly understood, to say nothing of possibly adding to the grave irritation already present in the adjoining nerve cells of the motor tract owing to the action of tetanus toxin. In at least one case death followed rapidly upon a thecal dose when the patient was said to have been progressing favourably. It was attributed to anaphylactic shock.

Although we have this decided impression that the intrathecal route may be a dangerous one and do not feel its theoretical foundations to be as secure as one would like, still we have a fair number of instances in which the reporting medical officer was struck with the apparent benefit following a thecal dose, and, of course, as our tables show, it has formed a part of the treatment in 27 cases which recovered.

If it is desired to employ this method we think that its use should be very carefully watched, that exceptional care should be taken to guard against possible contamination of the canal through the needle puncture, that the serum should contain no preservative, and that it is undesirable to withdraw more than 10-15 c.c. of cerebro-spinal fluid or to replace this by a greater volume of antitoxin. It might be advisable to employ for this purpose a solution of desiccated antitoxin, which would be free from preservatives, and could be rapidly prepared under sterile conditions in the desired concentration.

The subcutaneous and intramuscular routes may appropriately be considered together, as they are essentially similar in action, each being a comparatively slow and continuous method of dosage as distinguished from the rapid introduction involved in the venous and thecal methods. While we have expressed our unfavourable impressions in respect of these rapid methods, we have in the present case received a strongly favourable impression, which is confirmed to some extent by the results obtained in the home hospitals. Hitherto these two routes have been looked on as merely supplementary to the others and as being of chief value when it was desired to maintain a moderate concentration of antitoxin in the system after the critical period was past, and with a view to warding off a possible relapse. We think, on grounds both of theory and observation, that they might be promoted to a more dignified position. We believe our records show that when these two paths of introduction have been utilised freely, and where the dosage has been sufficient, the results as regards saving of life have been more satisfactory than when they were not utilised or were used in altogether too restricted a fashion.

Turning to the theoretical aspect, we may follow for a moment the path which the toxin is believed to travel on its way to the central nervous system. It is generally accepted that it travels by way of the motor nerves, though it is still a matter of debate whether it progresses through the axis

cylinders or through the lymphatics which accompany these nerves. At all events, the general blood stream and lymph stream are considered to play but a small part. Once the tetanus spores have found conditions suitable for their germination, and the bacteria themselves are multiplying without interference in some nook or cranny of the wound, the formation of the toxin goes on continuously. It is possible that this toxin at times may accumulate locally and only upon some local disturbance of the wound does it become absorbed in quantity, producing probably a rapid and fulminating attack. At other times the toxin may be slowly but continuously taken up by the nerves, as it is formed, and this may lead to a comparatively slow onset of the disease. In either case we have then to deal with a localised factory of the toxin, which is either continuously or discontinuously absorbed along the nerves. Looking now at the possibilities of neutralising this toxin, we have in our hands a perfect antidote, of that there can be no question, and the problem becomes clear that it is an affair of trying to bring antidote and poison in contact with one another within the shortest time and under the most favourable conditions for neutralisation to take place. The alternative lines of attack are three and no more—the local factory of toxin, the line of transit of the toxin to the central nervous system, and the central nervous system itself. The first would, of course, be the ideal one to select, but, unfortunately, we cannot locate it with precision, and attempts to reach it and to deal with it by surgical measures, or by the local application of various antiseptics or oxidising agents, more often than not end in failure or in a sudden outpouring and absorption of toxin. The last, the central nervous system, is difficult to reach and, at the best, this is an attempt to recapture from the enemy a position which they have already taken and hold in great strength. The method of intrathecal injection aims at such a local assault but depends for its possible success on two assumptions—namely, that the antitoxin shall actually come into contact with the nerve cells which are poisoned and, having come into contact with them, shall be able to neutralise or withdraw from these cells the tetanus toxin which had reached them. In practice the results of this line of attack appear to us, from our own and the home cases, to be most disappointing.

The chances of success by employing the third alternative, an attack on the lines of communication, would appear more hopeful, especially if this could be done by some method which would keep up the antitoxin attack steadily and continuously on the path over which it is probable the toxin must travel. To effect this there appear to be grounds for considering that the subcutaneous and the intramuscular channels offer greater prospects of success than the intravenous method, for the reason that the dose of antitoxin thrown into the veins is immediately diluted by the whole volume of the blood and, subsequently, of the lymph, and by the time any portion of it comes round to the site where it is required it must be very dilute indeed. On the other hand, antitoxin injected beneath the skin or into the muscles is said to be absorbed but slowly, taking, it is stated, 48 hours in the case of the subcutaneous site and 24 in that of muscular. This comparatively slow rate of dispersion of the antitoxin, presumably into the blood or lymph streams, is usually held to be a disadvantage, and it is largely on this account that the more rapid methods of venous or thecal injection have been advocated as more suitable for treatment in the early or acute stages. To us it appears that this slow rate of absorption should rather be counted as a virtue, especially when the inoculations are made somewhere along the supposed path taken by the toxin in its journey from wound to cord. At all events, it seems clear that by these methods we could in a given area produce a zone of tissue bathed in antitoxin in far higher concentration than could be produced in the blood and lymph of the part by means of intravenous injections, except perhaps by immense doses frequently repeated. Further, it is probable that this antitoxin would remain available locally in considerable strength for a number of hours. On the other hand, assuming that antitoxin is absorbed from the muscles with comparative rapidity, this would be a reason for utilising that channel in order to reach the nerve-centres rapidly, through the general circulation, in cases where it was hoped to effect an early dissociation of toxin from these centres.

Should the wound be a single one, and especially if it is on a limb, we believe it would be sound practice to introduce

antitoxin, both subcutaneously and intramuscularly, somewhere astride the path which the toxin must travel on its way to the spinal cord. To do this effectually it would appear, if our ideas are correct, better to divide the dose and inject portions on each surface of the limb and also at different depths amid the muscles. Somewhere among these tissues we know the nerves run along which the poison is travelling, and the more evenly distributed our antitoxin the better would appear the chance that it may attain effective contact with the toxin and achieve our object.

We have already mentioned that the results of these two methods of introducing antitoxin appear, in the present series of cases, to have been better than those of either the intrathecal or the intravenous methods. It may be that they would have been better still if employed alone, and on the lines suggested above.

Turning now to the question of dosage this appears a most difficult matter to judge. Cases recover in which the amount given has been almost ludicrously small, and others have died in spite of enormous doses. It appears to be a question of bringing the antitoxin into effective contact with the toxin. There can be no conceivable benefit in flooding the body fluids with antitoxin if this never reaches the site where it is required, and, on the other hand, quite a small dose might, by acting at the right time and in the right place, do all that was needed. There are obvious limits to the amount which one can inject intrathecally, but none by the other routes. On the whole, while admitting that we have little to guide us in the matter, we think that, if the combined subcutaneous and intramuscular routes be used, the daily dosage for the first few days should not fall below 10,000 units. If it be desired to supplement this by intrathecal injections it would appear wise to limit these to such a number of units as could be contained in 10 or 15 c.c.

We are in full agreement with all that has been said on the necessity for commencing specific treatment at the earliest possible moment and also on maintaining an effective dosage well into convalescence. The present series contained several examples of relapses occurring on the cessation of serum treatment. With regard to the recommendations of the Tetanus Committee as to watch being kept for early signs of tetanus, this is obviously of the first importance. In connexion with the present series of cases we have unfortunately received little fresh information on this point. A statement upon this point is now asked in every case, but so far has brought little to light. Practically the only early sign mentioned has been that of local contractures at or near the wound, and this has usually been followed rapidly by trismus. Some of the signs mentioned by the committee, such as pain in the wound and hardness of the tissues surrounding it, are, we fear, too common in connexion with sepsis, gas infection, &c., to possess as much value here as they might at home.

With the recommendations of the committee on the subject of repeating the initial prophylactic dose of antitoxin every six or seven days as long as there is any reason to fear tetanus, we are, we need hardly add, in the fullest accord. Instructions on this have been circulated to all concerned. Again, we agree that a preventive dose should be given prior to any secondary operation. For the reasons given above we think that it would be well to give such a dose by the combined subcutaneous and intramuscular channels, inoculating it at several points around the site of operation and at different depths of muscle on its proximal side. If time permitted this should be commenced 48 hours before the operation, but if the operation was one of urgency similar injections in the neighbourhood of the operation wound, with perhaps injection into the sheaths of prominent nerves, would appear a wise routine procedure. As far as present knowledge goes, 1500 units would be a suitable amount to give.

#### NON-SPECIFIC TREATMENT.

Although really outside the purpose of the present article, we may conclude with a few remarks on the replies which have reached us in connexion with this subject. Carbolic acid treatment has been almost abandoned, and few retain any faith in it. Its use was recorded in 8 cases, in strengths varying from 1-20 to 1-100. In no instance were any remarks made on its favourable influence upon the progress of the case. Magnesium sulphate also has gone out of favour, only 4 cases having been treated by this in July and 2 in September. The intrathecal route was

most often adopted. Some temporary amelioration of the symptoms and control of spasm was mentioned in 2 cases, but paralysis of the legs, lasting 24 hours, was noted in another.

Sedative drugs have been used in the great majority of cases. In order of frequency these were as follows: Chloral, bromide, morphia, chloroetone, atropine, omnopon, scopolamine, alcohol, chloroform, and paraldehyde. In some cases, though but few, it was noted that one or other of these drugs had been useful in controlling spasm.

Although fully sympathising with the natural desire of the busy reader to find at the end of a paper such as this a series of "conclusions," we have abstained from them, being very conscious that we have much more to learn on every point under discussion. However, we have not hesitated to express our own views on a number of these points as we have dealt with them, and we trust that they may at least serve to rouse further interest in the specific treatment of tetanus, which we believe to be of greatest value, did we but know how to apply it aright.

## MODIFIED TETANUS.

BY H. BURROWS, M.B., B.S. LOND., F.R.C.S. ENG.,  
CAPTAIN, R.A.M.C. (T.F.).

THERE are two reasons why the subject of tetanus should be of interest at the present moment. In the first place, the disease still occurs amongst the wounded. During the months of July, August, and September, 1916, at the General Hospital we had one case of tetanus in every 600 cases of gunshot wound. And this, of course, does not represent the full liability, for cases have occurred in patients who have been evacuated to England, and possibly at casualty clearing stations also. In the second place, a large proportion of the cases which have been seen recently have been abnormal in character, inasmuch as the muscular spasms have not become general. They have remained localised to the muscles in the neighbourhood of the original wound. Moreover, apart from the restriction of symptoms to the muscles in the vicinity of the wound, there are certain other characters which differentiate local or modified tetanus from the natural variety. These will receive attention later. In the meantime it may be remarked that in local or modified tetanus we have a new form of disease. The earliest record of a case<sup>1</sup> is now little more than three years old. The disease is new because its cause is new, for local tetanus is tetanus modified by the prophylactic use of anti-tetanus serum.

*Forms of modified tetanus.*—Cases of modified tetanus may be considered in three groups<sup>2</sup>—namely: (1) splanchnic tetanus; (2) cephalic tetanus; (3) local tetanus of the limbs. In all of these forms general spasms with opisthotonus are absent. Cases have been recorded which do not fall into any of these groups—for example, tetanus localised to the abdominal muscles. Nevertheless, these three groups will cover most of the ground and will provide sufficient material for discussion.

### 1. Splanchnic Tetanus.

Splanchnic tetanus<sup>3</sup> follows upon lesions of the viscera—that is to say, penetrating wounds of the abdomen and thorax. It is nearly always fatal and the course is exceedingly rapid, so that death ensues within 24 or 48 hours from the onset of symptoms. Opisthotonus and general convulsions do not occur, the spasms being limited to the muscles of deglutition and respiration. The difficulty in swallowing is a pronounced feature, and may be so severe that the case resembles one of hydrophobia, in which case the sight, or even the mere mention, of a glass of water causes the severest pharyngeal spasm; accompanied usually by acute dyspnoea.

### 2. Cephalic Tetanus.

Of head tetanus there are four varieties: (1) Non-paralytic; (2) the form accompanied by facial paralysis; (3) that accompanied by oculomotor paralysis; and (4) a form in which paralysis of the hypoglossal nerves is a special feature. Of these, the non-paralytic form is said to be the least common,<sup>4</sup> some motor paralysis being the rule in cases of head tetanus. And, as may be expected from its relatively wide distribution, the facial nerve is the nerve that is most commonly affected.

*Head tetanus with facial paralysis.*—This variety follows a wound of the face or its close neighbourhood, and is characterised by: (1) Unilateral trismus, which may become bilateral, and later on (2) difficulty in swallowing; (3) facial paralysis on the same side as the wound. The most remarkable feature is the fact that spasms occur in the paralysed muscles of the face. The explanation of this phenomenon is that there is an alteration in the conductivity of the peripheral branches of the facial nerve, which results in a partial nerve-block, sufficient to prevent the passage of voluntary impulses but insufficient to block the more powerful and pathological impulses of tetanus. The facial paralysis may persist after the other symptoms have disappeared, but ultimately, as a rule, the face recovers.

*Hypoglossal form.*—This form appears to be rare. As a matter of fact, in Major Kazanjian's Jaw Clinic there has never been a case, although the wounds treated there are of the kind in which hypoglossal tetanus might be anticipated.

*Ophthalmoplegic form.*—Ophthalmoplegic tetanus follows wounds of the orbit or its immediate neighbourhood. Ptosis is said to be the commonest symptom, but any or all of the ocular muscles, extrinsic or intrinsic, may be paralysed.

### 3. Local Tetanus of the Limbs.

The last abnormal form of tetanus is that which is limited to one or more of the limbs—that is to say, to one arm, or to one leg, or to both legs. These have been described as the monoplegic and paraplegic types. I do not know whether tetanus limited to the two upper extremities ever occurs. And as regards the simultaneous affection of one arm and one leg—a hemiplegic form—it is difficult to see how this could come about except as the result of simultaneous lesions of these two members.

The chief symptoms of local tetanus are clonic and tonic spasms of the wounded limbs. The clonic spasms have been described in some of the recorded cases as being accompanied by considerable pain, and as lasting for four seconds. As a matter of fact, in the four cases we have had at the General Hospital the clonic movements have been painless and have been mere twitchings, lasting, perhaps, for half a second each. In three out of the four cases these twitchings were the first symptoms to be noticed, while in the fourth case the patient complained that his arm was stiff, and it was found that spasticity and twitchings were both present. In the two cases which survived the twitchings gradually became less frequent with the passage of time, while the spasticity became more pronounced and showed no sign of passing off so long as the patients remained under our observation.

*Tetanic spasticity.*—In the two fatal cases no tonic spasm at all was observed. It is quite possible that in some cases twitchings may not occur, or may escape observation, and the spasticity may then be the only material result of the tetanus. And unless attention be directed to this possibility, it is likely that the true cause of the tetanic spasticity may be overlooked, while in some recorded cases the tonic spasm has preceded the twitchings, and from these facts it is recommended that "persistent hardness in a recently wounded limb should suggest tetanus." The most likely error is to mistake tetanic rigidity for hysterical spasm, which it closely resembles. But in this connexion it is to be noted that tetanic spasticity does not pass off during sleep—at least it did not so pass off in our cases.

There is a special reflex which is indicative of tetanus, and which may be of help in diagnosing certain cases. This reflex consists of extension of the foot and leg when the sole is stimulated, and is in contrast with the normal reflex, which is a withdrawal of the foot from the stimulus. The knee is placed in a position of slight flexion while the stimulus is applied to the sole. There is another sign which Lieutenant B. S. Simmonds has pointed out, and which is elicited as follows: Suppose the leg to be affected; light touches, even the lightest with a wisp of cotton-wool, will produce reflex spasms in that leg. To bring about the spasm by stimulating the thigh, a more vigorous application is necessary; for example, tapping the skin with the fingers. And the further away from the affected part that the stimulus is applied, the more vigorous must it be to evoke reflex spasms. I have thought that respiration of automatic type is an early sign, and believe that it may precede even trismus, and be the first positively recognisable evidence of the onset of tetanus.

*Post-tetanic anaesthesia.*—In the two non-fatal cases of local tetanus of the limbs which we have had at the — General Hospital areas of cutaneous anaesthesia remained. The question arises as to whether this anaesthesia is a consequence of the disease apart from gross trauma of the peripheral nerves. In our cases, the wounds were deep wounds and the cutaneous anaesthesia may have been due to direct injury of a nerve in the wound area. This important point can be cleared up only by further careful observation of cases of local limb tetanus when direct injury of nerves supplying anaesthetic areas can be excluded.

*Notes of Cases.*

The following brief notes on the cases of abnormal tetanus which we have had at the — General Hospital may be of interest. They are six in number, and include one case of splanchnic tetanus, one of head tetanus, and four of tetanus localised to the limbs.

**CASE 1. Splanchnic tetanus.**—The patient was an officer who had been wounded on Sept. 15th in the abdomen. Laparotomy had been performed and some perforations of the small intestines had been sutured. 500 units of antitetanus serum had been administered. We admitted him on Sept. 23rd, when the abdominal wound was cleanly healed. Three days later, 11 days after receipt of the wound, at 5 P.M. he complained of having a stiff jaw. Definite trismus was present and pharyngeal spasm was a pronounced feature. He rapidly became worse and died at 1.30 next morning—that is to say, 8½ hours after the first symptoms had been noted. He had no opisthotonus or general spasms. Death was preceded by unconsciousness and stereotyped breathing.

**CASE 2. Cephalic tetanus.**—The patient was wounded on Sept. 25th by a fragment of shell, which entered his face just above the left temporo-maxillary joint, penetrated the temporal bone, and passed upward into the temporo-sphenoidal lobe of his brain. On admission he had aphasia and weakness of the right upper extremity. On the 30th his skull was opened and the foreign body was extracted. Six days later—that is to say, 11 days after being wounded—tetanus developed. 750

units of antitetanus serum had been given to him at the casualty clearing station shortly after the receipt of his wound. The first symptoms were clonic spasm of the left facial muscles and trismus. On the following day there were added to the facial spasms incessant masticatory movements of the lower jaw and lips, in the course of which his tongue was severely bitten. It was thought—the patient thought so himself—that his tongue took part in the spasmodic movements. Two days later he had left facial paralysis, with spasms of both sides of the face, those on the right side being most vigorous. The left sterno-mastoid had become spasmodic also. On Oct. 22nd, 16 days after the onset of symptoms, the spasms ceased, but left facial paralysis remained.

*Local tetanus of the limbs.*—The four following cases are examples of local tetanus of the limbs:

**CASE 3.**—Patient was wounded in right hip on July 1st. On the 5th the wound was freely opened and a fragment of shell removed. On the 8th, seven days after the wound had been received, twitchings commenced in the right lower limb, and soon involved, though to a lesser extent, the left lower limb. Two days later the patient's pulse became weak, he became unconscious, and died. The twitchings, which were painless, continued up to the time of death, but they remained localised to the lower extremities, and he never had trismus, opisthotonus or spasms, other than those affecting the two lower limbs.

**CASE 4.**—Patient was admitted on July 4th with a gunshot wound of the left knee, penetrating the joint. The knee-joint was septic, and was treated by incisions and fixation. He had been given antitetanus serum before his admission. On July 10th twitching began in the left leg and foot. On the following day the right leg and foot were also involved, and amputation was performed through the left thigh. Three

days later the patient died. Since the amputation the twitchings had continued in the right foot and leg. He never had any trismus or opisthotonus.

**CASE 5.**—An officer had been wounded slightly in the face on July 1st, and had been given antitetanus serum on the following day. He was again wounded by fragments of shell in the calf of the left leg and the left thigh ten days later. On this occasion no serum was given. On the 25th, 14 days after the second wound, the left foot and leg began to twitch. During the spasm there was plantar flexion of the foot, dorsal flexion of the toes, and flexion of the knee. The twitchings were painless. Gradually the affected muscles became spastic, so that a week after the onset they no longer became relaxed between the spasms. The twitchings, as time went by, became less obvious, until they were no longer noticeable, but the tetanic rigidity remained unaltered up to the time of the patient's evacuation to England on Sept. 9th, three months after the receipt of his wound. There was anaesthesia to light touch of the heel and inner side of the foot.

**CASE 6.**—This patient is the subject of the illustrations. (See figures.) He had been wounded on July 23rd in the face and back, where there was an entry wound at the vertebral end of the spine of the right scapula. There was no exit wound. He had been given antitetanus serum on the day following the receipt of his wound. On August 14th, 22 days after being wounded, he complained of stiffness of the right arm, which was then observed to be twitching and to be spastic, with the arm slightly abducted from the trunk and the elbow flexed. The spasm could be overcome by steady traction until the arm was fully extended without causing the patient any pain, but as soon as the traction ceased the arm resumed its spasmodic position. In the course of the next few days the right trapezius and sterno-mastoid were observed to be twitching and to be tonically contracted also, causing elevation of the right shoulder and flexion of the right side of his neck. The twitchings were last noticed on Sept. 6th, but the tetanic rigidity remained undiminished up to the time of the patient's evacuation to England. Throughout there was cutaneous anaesthesia to pin-pricks and light touch over the area of distribution of the fourth cervical nerve.

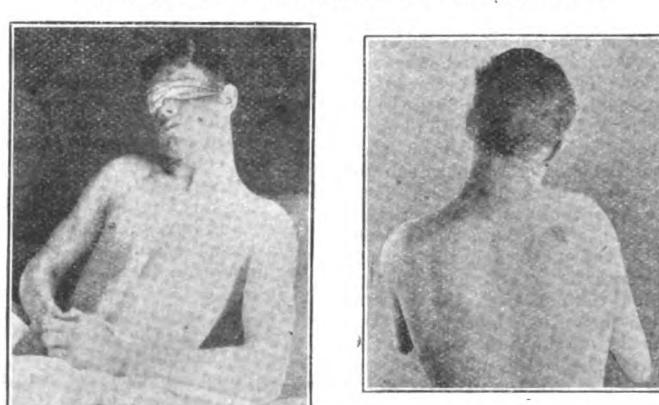

*Incubation period.*—The incubation period in the fatal cases varied from 6 to 11 days, the average being 8 days. In the non-fatal cases the incubation period varied from 11 to 22 days, the average being 16, so that the prognostic significance of a short incubation period appears to be identical in local and general tetanus—that is to say, so far as these few cases indicate.

*Duration.*—The duration of the disease in the cases which recovered, estimated by the period during which twitchings were observed, was between three and four weeks. It is difficult to be more exact, because the twitchings did not suddenly cease; they gradually became less frequent, less easily evoked, and less violent, so that their final disappearance was not a striking event to which a definite date could be affixed. The tonic spasm continued unabated so long as the patients were under our care.

*Mortality.*—The mortality was 50 per cent. This seems a peculiar fact, especially so inasmuch as the patients did not die of exhaustion from general spasm or from respiratory spasm. Presumably they did not die of sepsis in the ordinary sense of the term, for one had a clean amputation stump, and another had a healed abdominal wound, as the only source from which such septic absorption could have been derived. On the whole, it seems probable that the cause of death was tetanus toxæmia, causing a medullary paralysis, though I have not seen any previous reference to this mode of death from tetanus.

*Theoretical Considerations.*

In discussing the subject of local tetanus a great many points of interest will arise. For local tetanus, as has been

Front view.

Back view.

stated already, is a new form of disease. It is tetanus modified by the prophylactic injection of antitetanus serum. And it is the general adoption of this prophylactic treatment that has given us the opportunity to study the conditions. Cases of tetanus beginning locally and followed by trismus and general spasms have long been described, but pure local tetanus is a new thing so far as man is concerned. It is not unknown in animals. In the cat, which is relatively insusceptible to tetanus, a sub-fatal dose of tetanus toxin produces a persistent tonic spasm of the injected limb, and nothing else. And the same is true of the guinea-pig, if the dose of toxin be immediately followed by a sufficient dose of antitoxin. From which facts we may assume that the localisation of tetanus in man, as in the cat and guinea-pig in these experiments, is due to the presence of tetanus antitoxin in the blood.

We have still to consider why, with antitoxin circulating in the blood, there should develop any tetanus at all, and the solution of this question has been provided by experiments on animals. These experiments show that there are two avenues of approach whereby the toxin of tetanus may gain access to the central nervous system. These two avenues are: (1) The general blood stream; (2) the motor nerves. If both these avenues are open general tetanus will ensue. If both are closed, there will be no tetanus. If No. 1 is closed while No. 2 is open, local tetanus will result. Further, the route by the general blood stream is more easily barred than is that by the motor nerves. For toxin circulating in the general blood stream is readily neutralised by antitoxin present in the same medium, whereas the toxin, once it has gained entrance to a motor nerve, is almost insusceptible to the neutralising action of antitoxin. And it has been shown also, that when tetanus toxin is injected into a muscle, its passage into the nerve is rapid, so rapid that it may forestall the antitoxin and bring about local tetanus. Incidentally, it would seem that local tetanus is not likely to occur at all unless there is direct injury of muscle tissue—that is to say, if the hypothesis of causation is correct, local tetanus is unlikely to follow, for example, a wound involving skin and subcutaneous tissue only. Observations on this point are desirable.

Some hold<sup>6</sup> that the peripheral nerves are the sole means of entry of tetanus toxin to the central nervous system, and they explain the absence of generalised tetanus after subcutaneous administration of antitetanus serum as due to immunisation of the higher centres thereby, this immunisation being insufficient to overcome the relatively concentrated attack on the cord at the place of origin of the motor nerves. So far as treatment is concerned, it is immaterial whether this or the foregoing hypothesis is the correct one.

#### *Can Tetanus following Gunshot Wound be Abolished?*

General experience has shown that a great diminution in the occurrence of tetanus has followed the systematic use of antitetanus serum in cases of gunshot wound. There is strong evidence that it can be abolished, provided that two conditions are fulfilled. The two conditions are:—

(1) Firstly, that the initial dose of antitetanus serum is given sufficiently soon after the infliction of the wound. It has been shown that once the toxin has entered the motor nerves, or the central nervous system, it is not readily neutralised by antitoxin, and while we may suppose that tetanus bacilli require a little time to become established in a wound and to produce a material amount of poison, it also requires a certain period of time for antitoxin, injected subcutaneously, to produce much effect. It is stated<sup>7</sup> that with subcutaneous injections of tetanus antitoxin, as with similar injections of antidiphtheritic serum, two days are required for a maximum effect.

(2) The second condition is that the dose must be repeated. Tetanus antitoxin does not persist indefinitely in the blood. It disappears rather rapidly—ten days is given as its average time of endurance—and therefore the dose must be repeated at intervals of a week or thereabout, to ensure the maintenance of a proper amount of antitoxin in the blood. For by injecting antitoxin we do not destroy the tetanus bacilli in a wound. These continue to flourish, and to manufacture their toxin in spite of it, and have been found in a vigorous and virulent condition for as long as six weeks after the wound was received.<sup>8</sup>

*Duration of effect of antitoxin*—Ten days have been given as the period during which a single dose of antitoxin is effective. This, of course, is a general rule only. In the

third case of local tetanus (Case 5) the patient had been given a dose of antitoxin nine days before receiving the wound from which modified tetanus developed, and 23 days before the first symptoms appeared. From which it appears that antitoxin in some cases may remain potent in the blood for more than ten days; potent, that is to say, to prevent general tetanus. Perhaps it may last a great deal longer than this, as the following case seems to indicate.

A man was wounded in the foot in November, 1915, and was given antitetanus serum. On July 2nd, 1916, he received slight wounds in the back of his neck. He remained with his battalion, and no serum was given. On Sept. 14th stiffness of the jaws and difficulty of swallowing developed, for which he was treated at a casualty clearing station. These symptoms lasted for about ten days, and then passed off without the development of any grave consequences. Presumably this was a case of modified tetanus, although eight months had elapsed between the injection of antitetanus serum and the receipt of the second wound, and ten months between the injection and the first appearance of symptoms.

I have not included this among our cases of local tetanus, because the chief symptoms had disappeared by the time that we admitted him.

On the other hand, there is clear evidence that not only local but general tetanus may in some instances follow a gunshot wound, in spite of a single prophylactic dose of antitetanus serum.

We had such a case in 1915, in which general tetanus developed 21 days after a gunshot wound of the forearm, although a prophylactic dose of antitetanus serum had been administered shortly after the receipt of the wound. This patient, an officer, was a chemist in civil life, and was absolutely sure that an initial prophylactic dose of serum had been given to him.

*Site of injection.*—Judging from the knowledge gained by experiments on animals, there seems to be some advantage from injecting the serum in the first instance into the muscles of the wounded limb. This certainly seems to be advisable in cases where, for any reason, delay has come about in giving the initial dose; for example, in the case of a wounded man who has lain out for some days after being wounded.

#### *Treatment of Established Tetanus.*

In a case of established tetanus we must remember that, although the symptoms are local at first, they may become general. And, therefore, for purposes of treatment we cannot always differentiate between local and general tetanus, and we are not likely to be wrong if we assume that the patient is threatened with the greater evil. And this is so, even though it be stated on the patient's field medical card, that antitetanus serum has been given. For the administration of these prophylactic doses is often carried out by others than qualified medical men, a circumstance which is unavoidable, and yet carries with it the possibility of technical error. Moreover, as shown above, general tetanus may sometimes follow in spite of the proved use of prophylactic treatment.

The indications are: 1. To neutralise the toxin which is present in the circulating blood. 2. To neutralise the toxin which is passing into the nerves of the injured part. 3. To neutralise as soon as possible the toxin which has already reached the central nervous system.

Subcutaneous injection is too slow in its action to effect any of these objects, for speed is of urgent importance, and if no time is to be lost at all it will be necessary to employ three methods of introduction—namely, (1) intravenous; (2) intramuscular, i.e., into the muscles of the affected limb; (3) intrathecal. A suitable treatment would be the immediate intravenous injection of 3000 units of antitetanus serum, accompanied by the introduction of similar amounts into the spinal theca and muscles of the affected limb.

#### *Anaphylaxis.*

What dangers are to be feared from anaphylaxis? Personally, I believe that unless precautions are taken there is a real danger—in the case of intravenous injections, at any rate, of causing anaphylactic shock by secondary doses. I believe cases of sudden death to be examples of anaphylactic shock and to indicate that the secondary injection of antitoxin into a vein, in the presence of anaphylaxis, is a dangerous procedure unless certain precautions be taken.

*Recognition of anaphylaxis.*—How can we know if anaphylaxis is present? We can assume its presence if the patient has had a dose of serum ten or more days previously. As to the length of time during which anaphylaxis will continue there seems to be no definite information. Nevertheless, as anaphylaxis is present in some individuals to whom no serum has been administered previously, it is necessary to take special precautions in all cases in which the intravenous route is used for the injection.

By the following method danger from anaphylactic shock is said to be avoided.<sup>9</sup> 5 c.c. of antitoxic serum are diluted with 50 c.c. of warm saline. 1 c.c. of this is run into a vein. 4 minutes later 3 c.c. are run in; 2 minutes later 10 c.c., and 2 minutes later again 25 c.c. are run in, and after a pause of 10 minutes the remainder is injected. After this the intrahecal and intramuscular injections may be made without further special precaution against anaphylactic shock.

For some hours following the performance of intrathecal injection of antitetanus serum, it is necessary, of course, to keep the foot of the patient's bed well raised. We know, from experience with spinal anaesthesia, that fluid injected into the lower portion of the spinal theca will not travel up the cord if the patient's dorsal spine be raised above the level of his lumbar spine. We also know that the fluid will travel up if the foot of the bed be raised. And what is true for a solution of novocain we may assume to be true of a solution of tetanus antitoxin.

Besides the administration of antitetanus serum, other therapeutic measures need consideration. Of drugs, chloral, bromide, and morphia have been the most used. For procuring rest paraldehyde in large doses has seemed of great benefit, and is perhaps more effective than any other drug. In severe cases a watch must be kept for acidosis, which is said to be present, as might be expected, in most of these.<sup>10</sup>

Treatment of the wound also is of importance. The natural impulse is to operate at once in order to eradicate the offensive bacilli, to excise necrotic tissue, to remove foreign bodies, and to provide free drainage; or to amputate the limb, but caution is required here, for experience has shown that operations on wounds infected with tetanus bacilli are likely to bring about a sudden diffusion of toxin, with consequent disaster. And the same is true of amputation, even though the amputation be performed before tetanus has declared itself. Operations, therefore, should be deferred, if possible, in all cases of established tetanus until sufficient time has passed for artificial immunisation to have been effected.

Immobilisation, however, so far as this is possible, is of paramount importance. We know the ill-effect of movement in the case of wounds infected with tuberculosis or the organisms of sepsis, an effect which consists of diffusion of toxins and possibly of bacteria also. A similar effect ensues in the case of wounds infected with the bacilli of tetanus. And not only the wound but the patient also, so far as is possible, must be kept at rest. In general illustration of this point may be quoted a case that we had in 1915.

The patient, an officer, had passed successfully through an attack of general tetanus. After the symptoms had subsided and we regarded him as cured he was evacuated to England. On his arrival there tetanus again developed, and he underwent a second attack, brought on, there is little doubt, by the disturbances of his long journey.

#### Conclusion.

In conclusion, I should like to ask the following open questions:—

1. What cases of modified tetanus have been met with?
2. What have been the special features?
3. Have areas of cutaneous anaesthesia been observed in these cases?
4. Has persistent tetanic rigidity been present?
5. What is the cause of death in fatal cases?
6. Have any cases of anaphylactic shock been observed, and, if so, in what circumstances?
7. Have any cases of sensory tetanus been observed?

Answers to these questions I hope will be forthcoming, and also a great deal of other information on this interesting subject of local tetanus. If we are to understand the condition thoroughly, we must learn about it now, while there are cases available for study. It is to be hoped, therefore, that medical men who have had cases under their care will forthwith publish the details, and so communicate to others the benefit of their own experiences.

## WEIL'S DISEASE (SPIROCHÆTOSIS ICTERO-HÆMORRHAGICA) IN THE BRITISH ARMY IN FLANDERS.\*

BY A. STOKES, M.D. DUB., F.R.C.S. IREL.,  
CAPTAIN, ROYAL ARMY MEDICAL CORPS;

J. A. RYLE, M.B., B.S. LOND.,  
CAPTAIN, ROYAL ARMY MEDICAL CORPS, SPECIAL RESERVE  
AND

W. H. TYTLER,  
CAPTAIN, CANADIAN ARMY MEDICAL CORPS.

A SHORT preliminary note<sup>1</sup> on infectious jaundice among British troops in France was written in the early summer of 1916. Although the investigation of this disease is still being pursued both here and elsewhere and is as yet far from complete, the accumulation of considerably more material, both clinical and experimental, since our last publication would seem to justify a further communication at the present moment. The additional results which we have attained contain little not already described by Inada and his collaborators, but they seem of interest in that our confirmation of the findings of the Japanese workers, at the time of our first note only partial, has now been rendered almost complete. The only results which we have not been able to duplicate are their success in growing the causal organism in artificial culture and the finding of spirochaetes in the urine. The possible explanation of the former point and the evident explanation of the latter are discussed below.

#### Previous Work.

The disease commonly bears the name of Weil, who described it in 1886, but Martin and Pettit, in a recent publication discussed below, point out that this is quite unjust in that several French authors, quoted from Kelsch (1894), had previously described the condition under various names, and at dates extending from the siege of Cairo down to 1886. Those quoted are: Larrey, Ozanam (1849), Monneret (1859), Laveran the elder (1865), Lancereaux (1882), Landouzy (1882), and Mathieu (1886).

Weil described the chief characteristics of the disease as being jaundice, pyrexia, and haemorrhages, and the occurrence of cases in epidemics or localised groups. Widespread epidemics have been recorded in the United States, and also outbreaks in India, Africa, and the Near East. In Osler's Medicine we find:—

The symptoms are at first gastric, then fever follows (with the usual concomitants) and jaundice, which may be slight or very intense, and, as a rule, albuminuria. The liver and spleen are often enlarged, and in the severe forms there are nervous symptoms and haemorrhages. There is often a secondary fever, and the attacks last from ten days to three weeks. The course is usually favourable; fatal cases are rare in the United States and in India and South Africa, but in the Greek hospital at Alexandria the death-rate was 32 among 300.

No definite etiology had been established until the subject of infectious jaundice was reopened by a monograph from Drs. Inada, Ido, Oki, Kaneko, and Ito, which was first published in the English language in March, 1916, in the *Journal of Experimental Medicine*. In this paper the authors state:—

In the western part of Japan there prevails an epidemic and endemic disease, characterised by conjunctival congestion, muscular pains, fever, jaundice, haemorrhagic diathesis and albuminuria, which is known as Weil's disease or febrile jaundice. At the end of last year (1914) the same disease was observed in Shiba, in the eastern part of Japan near Tokio, where the patients numbered 178.

\* Received for publication on Dec. 8th, 1916.

In 1914 Inada and Ito reported the discovery of a spirochæta in the liver of a guinea-pig which had been injected with the blood of a patient suffering from Weil's disease. They reported that they were able to repeat this finding with the blood of other cases, the animals developing albuminuria, pyrexia, and jaundice, and they were able to show the spirochætae in the liver and blood of the animals in large numbers. They were able to pass the infection from animal to animal, and in one strain they had reached 50 passages. The experiments made with the blood of normal people and of patients with catarrhal jaundice produced no such result. Subsequently the Japanese workers were able to demonstrate "the same spirochætae in six specimens of patients' blood, in the intestinal wall of one case, and in the adrenal gland of another case, of 11 autopsied cases." In two cases which came to autopsy on the sixth day of illness they found the spirochætae in the liver in almost as great numbers as in the liver of guinea-pigs. Finally they showed that the blood serum of patients recovering from the disease contained protective substances against the spirochætae.

From these data they came to the justifiable conclusion that the spirochæta which they had found was to be considered the causal organism of the disease. They state that they have, with the blood of 13 out of a series of 17 cases, succeeded in producing the disease in guinea-pigs, the animal showing the typical signs of the disease and the spirochætae being found in the blood and liver. The blood from all cases in which it was taken on the fourth or fifth day of illness gave positive results, but after the fifth day the results became more inconstant as the disease progressed. They indicate that the spirochætae disappear from the blood coincidentally with the appearance of immune substances in the serum. In the early stages the spirochætae were in the blood stream, but as the disease progressed they disappeared from the blood, and the authors were not able to demonstrate them in the tissues. At some period after the tenth day spirochætae appear in the urine and may be demonstrated both by dark-ground illumination and by animal inoculation. They consider the appearance of the spirochætae in the urine to depend on the development of an immune substance in the serum. They have been able to find spirochætae in the urine as late as the thirtieth day.

Weil believed that the entry of the infection was through the alimentary canal, and Inada supports this view. Ido and Oki have noticed that the disease sometimes begins with a local swelling of the lymph glands, and, further, they have been able to communicate the disease to animals by applying infected material to the uninjured skin. This led them to think that there was a possibility of infection occurring through the skin. In support of this view they note that the disease was more frequent in the wet parts of certain mines, and that, the water having been pumped out on their suggestion, no further cases occurred in those particular areas. They also noted that there were more cases in wet mines than in dry, and that men working on the surface did not contract the disease. They think from clinical observation that direct infection from man to man is rare. Without stating their reasons they say that they consider transmission by mosquitoes or by vermin unlikely.

In the *Bulletin de l'Académie de Médecine*, Oct. 10th, 1916, Dr. L. Martin and Dr. A. Pettit have published an interesting note confirming the existence of the disease in the French Army. They have followed two cases in full and succeeded in finding the spirochætae in the urine and in infecting with the urine of patients convalescent from the disease. They further add an important link to the epidemiology of the disease in describing a most interesting case of one of their colleagues, who himself became infected in passing the disease from animal to animal, the circumstances leaving no doubt that the period of incubation was six to eight days.

#### *General Clinical Picture of the Disease.*

Our attention was first called to the disease by a fatal case of jaundice under the care of Captain Flood, R.A.M.C., whose permission we have for mentioning the case.

The man was admitted with a temperature of 105° F. and very deep jaundice. On the evening of admission there was severe epistaxis, which necessitated the plugging of the nares. Haemorrhagic diarrhoea set in, and on the third day after admission the trunk and limbs were covered with

petechiae. Death followed on the next day. Multiple haemorrhages in the pleura, pericardium, and peritoneum were the most striking feature, apart from the extreme jaundice of all the viscera. The bile passages were free and the duodenum normal. This is the only case we have seen in which the generalised haemorrhages occurred in more than trivial degree, and in this case haemorrhagic diarrhoea was apparently the immediate cause of death. At the time there were no guinea-pigs available for inoculation and the tissues from the case were unfortunately lost. An emulsion of the liver and kidney examined by dark-ground illumination revealed no spirochætae.

A second case, also fatal, occurred a few days later; the patient was admitted moribund under the care of Major Young, C.A.M.C., and died within a few hours. The autopsy showed nothing significant with the exception of the extreme jaundice of the viscera and advanced haemorrhagic nephritis. Tissues examined for us by Dr. Laidlaw at Guy's Hospital did not reveal any spirochætae, and this is in accordance with the findings of the Japanese workers who state that it is very difficult to find the spirochætae when the patient dies late in the disease, as happened in this case which terminated on the twelfth day.

Since then about 100 cases have been observed by us, and of these 50 have been under the personal care of one of us (J. A. R.). In 26 cases we have infected animals from the patients. The animals have died or have been killed, and have all shown the characteristic picture of the disease in the animal, and we have been able to find the spirochætae in all of them, either in films or sections of the tissues. Early in our observations we were struck by the occurrence of cases showing a similar clinical picture, but no jaundice, and we have since been able to establish the fact that cases of spirochaetosis occur without external signs of jaundice, which would seem to cast a doubt on the accuracy of the terms epidemic jaundice and spirochaetosis icterohaemorrhagica. We cannot say definitely in how many cases of Weil's disease jaundice occurs as a clinical sign, but we estimate that it does not occur in more than 60 per cent. of cases in the epidemic with which we are dealing.

*The onset.*—The history of onset was strikingly uniform, and the acuteness of the inception of the disease may be judged from the fact that the patients almost invariably were able to date the onset by some simple reference to the duty they were performing at the time. The onset is very commonly heralded by a shivering fit and a feeling of faintness or giddiness. Characteristic early symptoms have been vomiting, headache, and pains in the back and limbs. The patients complain of great weakness and of feeling as if they had been beaten all over, and they are so sensitive to these pains that they are reluctant to move their limbs or to turn over in bed. Pain in the eyes is a frequent early symptom, and there are often vague unlocalised abdominal pains. The onset is generally with fever of a more or less high degree, varying between 103° and 105° F. The limb pains appear to be muscular, but in one case were especially referred to the tibiae. All the patients on admission were very weak and often collapsed, and complained of the early feeling of unsteadiness and inability to stand.

*Alimentary system.*—The tongue is excessively dry, brown in colour, frequently fissured, and there are sores on the lips. Herpes labialis, invariably becoming haemorrhagic, occurred in 42 per cent. of cases. Vomiting in the early stages may be said to be a constant symptom; it often persists for several days, and the vomitus is frequently bilious. A history of blood in the vomitus is occasionally elicited, and streaks of blood have been seen, but as this may have been swallowed from the naso-pharynx it was not noted as a true haematemesis. Appetite, which was lost during the pyrexial period, returned as the jaundice faded. Hiccough occurred in the two most severe cases, one of which terminated fatally.

Except in two cases, in which there was a history of initial diarrhoea, extreme constipation was the rule throughout the acute stage of the disease. The stools were usually bile-stained. One fatal case succumbed to a terminal haemorrhagic diarrhoea, and in one other small traces of blood were observed in the stools. Intestinal haemorrhage may therefore be regarded as exceptional. During the first few days many patients complained of vague abdominal discomfort and pain, but there was never any localised tenderness. Abdominal examination revealed distinct hepatic enlargement in one case without jaundice, but in no other case was the liver palpable. The spleen was not palpable in any case while under observation here.

*Circulatory system.*—The pulse-rate is usually slow in proportion to the temperature, and this holds good even in the cases without jaundice. In one severe case the pulse-rate rose to 120 during the first week. In early convalescence there is a definite diminution in the pulse-rate. Even

In the bad cases the tension and volume are good. Marked diastole was once noted. Except in one case in which the apex beat was for a short time external to the nipple line, there was no clinical evidence of cardiac dilatation.

*Respiratory system.*—There is, as a rule, no evidence of respiratory complications beyond slight bronchitis in the severer cases or haemoptysis. The respiratory rate is sometimes raised during the early stages, but there was never any evidence of consolidation or pleurisy. In 26 per cent. of cases there was blood-tinged expectoration. Both "bright-red" and "rusty" sputa were noted, the latter being the more common. In the two cases in which hiccough was noted a peculiar catch type of inspiration occurred, and in two others there was an expiratory grunt, although no other pneumonic symptoms were present. Epistaxis occurred in 17 per cent. of cases.

*Excretory system.*—Two cases had difficulty in micturition for which there was no obvious cause. The urine of jaundiced cases contains bile in varying quantities. In some the urine is very deeply coloured, in others the colouration is less evident. In some of the cases without jaundice bile has been demonstrable in the urine. Albuminuria was almost a constant accompaniment of the pyrexial period and varied from a "faint trace" to a "considerable amount." Granular tube casts and red blood cells were present in centrifuged specimens. Probably as a result of the fever and vomiting acetone was also demonstrable in the urine of all the graver cases.

*Nervous system.*—Weakness and great prostration are characteristic of the onset of the disease. Headache and generalised pains and stiffness are constant symptoms, and the pains in the back and legs are exceptionally severe, frequently causing sleeplessness. In the graver cases torpor was noticed, and in one fatal case this progressed to the "typhoid state," and was accompanied by rambling delirium, tremors, and muscular twitches. Pruritus, probably due to the jaundice, occurred in three cases. The eyes are painful and show very marked injection of the conjunctiva, and in one case during convalescence there was a pink suffused zone round the sclero-corneal junction, associated with photophobia, and suggesting a definite scleritis. Subconjunctival hemorrhage occurred in one case.

*Lymphatic system.*—There is a slight enlargement of the glands. The pectoral group of the axillary glands are sometimes felt as discrete shotty nodules on the thoracic wall of the axilla. The cervical glands are also enlarged and sometimes tender. The spleen has never been palpable.

*The skin.*—Varying degrees of jaundice are seen. The colour is usually of a lemon-yellow to a deep orange tint, and never approaches the greenish colour of obstructive jaundice. It first appears on the fourth or fifth day of illness, occasionally earlier: it becomes progressively deeper until the ninth or tenth day, and then, as a rule, fades very rapidly. In some cases, however, the colouration is more persistent. Of 47 cases diagnosed as Weil's disease clinically, or by communication of the disease to the animal, 74 per cent. have developed jaundice, and 26 per cent. have not shown any colouration.

Hæmorrhagic herpes labialis, occurring in 45 per cent. of cases, was frequently of very wide extent, in some cases covering the chin and upper part of the neck. In one case the herpes formed a black, confluent eruption which completely surrounded the mouth and invaded the nares; the contrast of the black sores with the brilliant orange colour of the facies, together with the blood-shot eyes, gave the patient an alarmingly morbid appearance. Petechial hæmorrhages, widely distributed over the trunk, were present in association with the jaundice in one of our cases which recovered, and in one fatal case under Captain Flood. Profuse urticaria occurred in one of our cases.

*The fever.*—There is an irregular pyrexia descending by lysis, and ranging for the first week between 100° and 103°. Temperatures of 104° and over are common at the onset. The fever terminates between the tenth and fourteenth days, and is often succeeded by a subnormal temperature for three or four days. In four cases there was a relapse of the pyrexia but not of the other symptoms, but it must be remembered that the cases are evacuated at an early date, as soon as the pyrexial period is passed, and it may be that relapses occur more commonly than would appear from our observations. We insert some typical charts (Nos. I.-IX.) of jaundiced and non-jaundiced cases.

*Differential diagnosis.*—There is seldom any difficulty in distinguishing between Weil's disease and other forms of jaundice. The high pyrexia, prostration, and conjunctival congestion, on the one hand, and the absence of any localising symptoms, on the other hand, exclude catarrhal jaundice, gall-stones, and cholecystitis. Jaundice due to typhoid or paratyphoid infections is to some extent excluded by blood culture, which is usually done on admission. In the early stages, however, before the appearance of the jaundice and in the non-icteric cases the diagnosis is more

difficult. The combination of pyrexia, herpes, and hæmoptysis has not infrequently resulted in the patient being sent to hospital with the diagnosis of pneumonia, while others have been labelled pulmonary tuberculosis, suspected cerebro-spinal meningitis, and "trench fever." Between severe forms of "trench fever" and non-icteric spirochaetosis it is almost impossible to distinguish during the first few days unless the presence of vomiting and albuminuria in the latter and their absence in the former should prove constant.

*Prognosis.*—During the first two months in which we had cases under observation there were two deaths, and though during the following three months four-fifths of the total cases have passed through there have been no further deaths previous to evacuation as convalescent. We have heard of two cases which were evacuated during the pyrexial period and have succumbed elsewhere. On the whole, the prognosis may be said to be favourable even in the more severe cases. The death-rate is, so far as we know, less than 6 per cent.

*Treatment.*—The treatment at present is purely symptomatic. Good nursing, unlimited fluids, alkaline draughts, fruit to eat, and the rectal administration of glucose (6 per cent. solution, 1 pint) once or twice daily to cases with vomiting and acetonuria constitute the main elements of treatment in our series. When possible the patients are nursed in the open air with apparent benefit.

#### Clinical Pathology.

In order to attempt to ascertain if the jaundice was of hæmolytic origin we made daily blood counts in four early cases, the count being done on five successive days from the fifth to the ninth day of illness. We were unable to demonstrate any progressive diminution in the cell count or in the haemoglobin, and the average of the counts was high. Leucocyte counts in the early cases ranged from 9000 to 10,000 cells per c.m.m. Stained films did not show any degeneration forms or polychromatophilia, changes which are easily demonstrated in the infected animal. The coagulation-time was taken by Wright's method and ranged around 3 minutes.

The resistance of the red cells to various concentrations of salt solution was tested, and it was found that in the cases with jaundice the resistance was increased. Hæmalysis began in normal blood in 0·450 per cent. NaCl, and did not commence in patients with jaundice till 0·350 per cent., and was not complete at 0·300 per cent. This was not found to be the case in patients suffering from Weil's disease without jaundice, and by the addition of small traces of bile to normal blood cells it was possible to increase their resistance. The end-point of the hæmalysis was very low, "complete" being reached in 4 cases only at 0·250 per cent., whereas the normal controls were "complete" at 0·300 per cent. Blood cultures for enteric group organisms were made in over 50 cases, and were consistently negative at the end of three days.

We searched diligently in blood films for the spirochaetes, using different methods and staining in different ways. In one case after citrating a large quantity of blood (20 c.c.), and allowing the cells to settle, and then centrifuging the citrated plasma, we found one spirochaete and in confirmation the animal infected with the blood developed jaundice. This blood was taken on the fifth day of the disease. Dr. A. C. Coles examined films from two cases for us by his special method; in one, the films being made on the second day of illness, he was able to find two spirochaetes in six films. In the other case the films were made on the fourth day and no spirochaete could be found. He has included photographs of the two spirochaetes which he found in the set of photographs he has kindly sent us. We attempted to cultivate the spirochaete directly from the blood-stream on several occasions from early cases, but with no success.

*The urine.*—Albuminuria was a constant occurrence in varying degree; some cases showed only a faint trace, and in others there was a considerable quantity. Casts, generally granular, were frequently found, and a few blood cells were almost always present in centrifuged deposits. Bile pigments in the jaundiced cases were present in large amounts; in some of the cases without jaundice bile could be detected and in others it was absent. Acetone in considerable amounts was present in nearly all the severe cases during the pyrexial period. Leucin and tyrosin crystals were not found. We examined the stools of a series of cases for enteric group organisms but were unable to find them.

#### Morbid Anatomy.

Four cases terminated fatally which we were able to observe:—

Pte. M. Duration of disease unknown, died four days after admission with extreme jaundice and severe hæm-

rhages. Skin showed multiple petechiae and very pronounced jaundice of a bright yellow tint. Peritoneum, pericardium, and pleura covered with small bright-red haemorrhages; haemorrhages in the heart muscle and under the endocardium. Heart soft and flabby. Haemorrhages in the substance of the lung. Liver normal in size, colour, and consistency. Spleen small. Kidneys enlarged and swollen, with multiple haemorrhages, and deeply bile-stained. Intestines and bile-passages normal. All the

large polypi at the pyloric end, one of which had apparently been bleeding and looked like a large thrombosed pile. The heart was very soft and flabby. Two small haemorrhages in the mesentery, one in a lymph gland. Duodenum and bile-passages normal. No spirochaetes found in emulsions of liver and kidney by dark-ground illumination.

Pte. E. Died on ninth day. Extreme jaundice of skin, no haemorrhages. Lungs showed many diffuse, ill-defined haemorrhagic areas, 1 to 2 cm. across; they were most

CHART I.

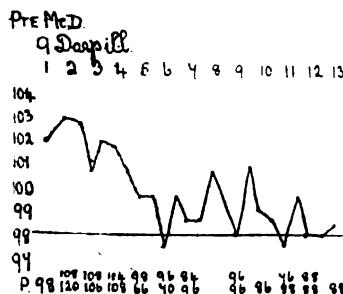

CHART II.

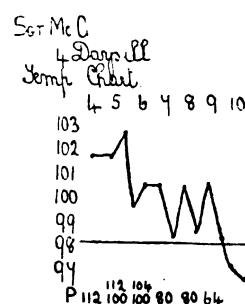

CHART III.

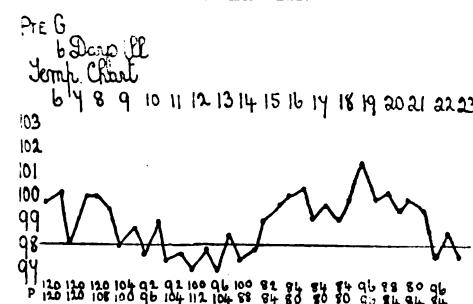

CHART I.—Private McD. Complete chart from first day. History of sudden onset, with shivering, severe pains in head and limbs, jaundice, haemorrhagic herpes, dry, brown tongue; no enlargement of spleen or liver.

CHART II.—Sergeant McC. Very extensive haemorrhagic herpes. Jaundice appeared on fifth day. Diagnosed clinically before jaundice appeared. Temperature chart of animal infected from this patient is given later. (See Chart XIII.)

CHART III.—Private G. Short relapse. Vomiting, jaundice, epistaxis, blood stained sputum, and enlarged glands; hiccup severe, dry mouth and torpor. On the tenth day jaundice began to fade. No return of symptoms, with exception of malaise, with rerudescence of pyrexia.

CHART IV.

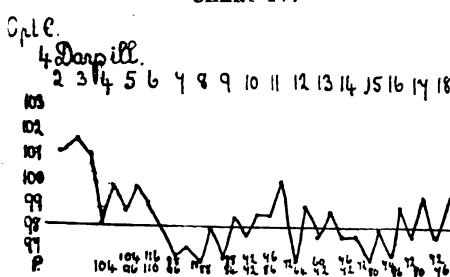

CHART IV.—Corporal C. Chart showing short relapse. Jaundice, herpes, vomiting, epistaxis, albuminuria, acetoneuria.

CHART V.—Private G. No jaundice; clinically diagnosed; intense headache, pains in legs and abdomen; liver slightly enlarged and tender; prostration great, injected eyes, albuminuria.

CHART VI.—Private H. Pains in back and legs, injected eyes, drowsiness; no jaundice. Temperature chart of animal infected from this patient is given in the section on the disease in animals. (See Chart XII.)

CHART V.

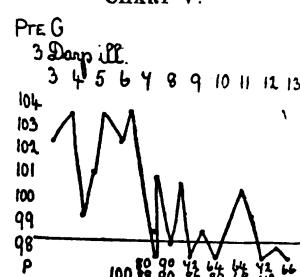

CHART VI.

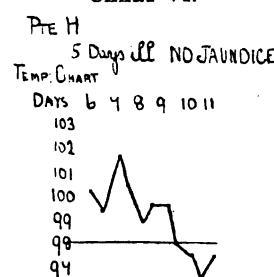

CHART VII.—Corporal McG. Non-jaundiced case. Admitted second day. Severe pains in head, eyes, back, limbs; albuminuria, haemoptysis, vomiting. Chart of animal infected from this patient given later. (See Chart XI.)

CHART VIII.—Private H. Fatal case. Aged 40. Admitted on tenth day with deep jaundice and general malaise, headache, and pains in the legs; onset with vomiting. On admission, conjunctive injected, tongue dry and furrowed; liver and spleen not felt; albuminuria. Twelfth day: Mental confusion, retention of urine, hiccup. Thirteenth day: Rambing delirium, retching, jaundice deeper, pruritus; dyspeptic attack. Fourteenth day: Incontinence of urine and faeces, muscular twitchings. Death supervened.

CHART IX.—Private E. Fatal case. Chart of animal infected from this case is given later. Admitted with jaundice and very ill; unable to give clear account of duration of illness; tongue dry and furrowed, eyes injected, generalized muscular pains; no enlargement of liver or spleen. Patient given alkaline drinks and 1 pint of 6 per cent. glucose per rectum. Next day patient worse; tremors, restlessness, retention of urine, and feeble, intermittent pulse; 1½ pints of 2 per cent. sodium bicarbonate intravenously. Died two hours later, probably on the eighth or ninth day of illness. (See Chart X.)

CHART VII.

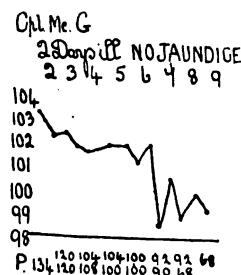

CHART VIII.

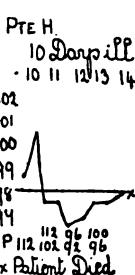

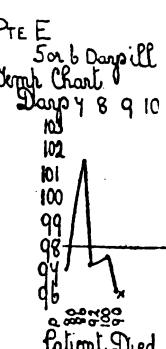

CHART IX.

internal organs, where the colour permitted of its observation, were deeply tinged with bile. No spirochaetes found in liver by dark-ground illumination.

Pte. T. Died on twelfth day. Jaundice somewhat more intense than in the last case. Nothing abnormal noted with the exception of the large, swollen, congested, and haemorrhagic kidneys. Intestines and bile-passages normal. No spirochaetes found in liver or kidney by dark-ground illumination.

Pte. H. Died on fourteenth day. Deep jaundice of skin and all viscera except the brain. Liver normal in size and colour. Spleen small. Kidneys large, swollen, congested, and showing multiple haemorrhages. Stomach had two

evident on the pleural surfaces, but were also well seen on the cut surface. One small haemorrhage in the wall of the left ventricle. Heart soft and dilated with deeply bile-stained endocardium. Liver normal in size and colour. Spleen small. Kidneys swollen, enlarged, and showing multiple haemorrhages. Intestine showed three patches of congestion of the mucosa, one of these in the duodenum. A few enlarged glands in the portal fissure and along the lesser curvature of the stomach. The bile-passages were free.

It will be seen that the haemorrhages, in varying degree, occurred in three of the four cases. An interesting point is that the brain was not bile-stained, though the cerebro-spinal

fluid was bright yellow. The tissues from two fatal cases are available for study; two other fatal cases occurred, but in one instance the tissues were lost and in the other the tissues were sent home for microscopic examination, and we have no sections now in our possession.

*The liver.*—(1) Pte. E. (see Chart IX.); (2) Pte. H. (see Chart VIII.). Both livers showed a certain amount of diffuse granular degeneration, though hardly of significant extent. The most evident anatomical change, as seen in Case 1, is an exudation of polymorphonuclear leucocytes in the interstitial tissue surrounding the smaller bile-ducts. The leucocytes are diffusely scattered and nowhere suggest abscess formation, but around a section of small bile-duct 8 or 10 cells in length there may be seen scattered often as many as 12 or 15 leucocytes. They seem to be more numerous around the smallest interlobular ducts. Leucocytes may also be seen here and there between the liver columns, but nearly always within the blood-vessels. The liver (Case 1) shows a very considerable quantity of bile-pigment, mostly within the cells, in the form of greenish-black rods and granular masses. A difference in quantity between different parts of the lobule could not be definitely demonstrated. Bile-pigment was also found in the blood-vessels and in what we take, after some consideration, to be distended interlobular bile capillaries. These are most evident at the periphery of the lobule, in the neighbourhood of the smaller bile-ducts. Thus, a bile-duct may be seen at its origin from the lobule, surrounded by leucocytes, and just within the lobule at this point there may be seen, lying between adjacent liver cells, three or four spaces up to the size of a liver-cell nucleus, distended with bile-pigment, and apparently converging towards the bile-duct. Case 2 shows considerably less interlobular leucocytic exudate and considerably less bile. There is, however, a moderate amount of light-green pigment filling many cells in the form of fine granules. The structures which we take in Case 1 to be distended bile capillaries are much less evident here, although two or three small circular spaces have been seen, each lying between contiguous liver cells and containing a small amount of pigment. Leucocytes are seen in greater numbers than normal, but diffusely scattered between the liver columns and usually between the vessels. Thus, a row of four or five contiguous leucocytes in a small capillary is not difficult to find. Congestion in neither liver is pronounced.

*The kidney.*—The kidney in each case shows, apart from the acute lesions, a moderately extensive, chronic, diffuse cirrhotic process, rather more pronounced in Case 1. The acute lesions consist in, firstly, swelling and granular degeneration of the tubular epithelium, much more evident in the proximal convoluted tubules and the ascending limbs of Henle's loops. The distribution is diffuse, practically every tubule being involved, so that with most of the tubules the lumen appears to be obliterated. Secondly, a diffuse exudation of polymorphonuclear leucocytes in small numbers, lying between the tubules and more rarely within them. Thirdly, hemorrhage occurring in poorly defined patches usually involving several tubules. The blood is found mostly within the tubules and widely distending them, particularly in the distal convoluted portion. In both cases there was, however, considerable dilatation due to the chronic process, so it is difficult to decide in how far dilatation due to hemorrhage occurred. All these changes were more marked in Case 1, where the degeneration of tubular epithelium was extensive. Glomeruli in neither case showed significant changes.

Sections of other organs showed no important changes, with the exception of the localised hemorrhages in the lungs of Case 1 noted in the gross.

*Spirochete in human tissue.*—Sections of liver, kidney, adrenal gland, and lymph nodes have been prepared by Levaditi's older method and have been thoroughly searched for spirochaete. We failed to find them in all tissues except the kidney of Case 1. In this kidney a small number of characteristic spirochaete were found in isolated areas, so that in an entire section they would be found only in the neighbourhood of one glomerulus, but in considerable numbers at that point. They lie very occasionally between the tubules, but the characteristic place is the epithelium or lumen of a proximal convoluted tubule close to its origin from the glomerulus. Thus in one section of a tubule there may be found as many as 10. Where several occur together in this manner, the majority seem to lie near the centre of the tubule among the granular débris. The tubules in which they are found as a rule show more than the average amount of epithelial degeneration.

#### Experimental Results.

Tables I., II., and III. show the results of the intraperitoneal injection in the guinea-pig of blood of patients clinically diagnosed as Weil's disease. Table I. gives the results from cases showing definite jaundice; Table II. those from cases without evident external jaundice; and Table III. the combined results of the two series.

What we mean by a positive result is that the animal should show the typical signs of the disease, jaundice and hemorrhages, and that we should find the spirochaete in the blood or liver, either in films or in Levaditi preparations of the tissues. We have found, as the Japanese workers did, that the intraperitoneal injection of comparatively small

quantities of blood gave the most satisfactory results. Various quantities have been tried, but our experience has led us now to employ as a routine a quantity of approximately 3 c.c. Larger quantities have not yielded better results and have often killed the animal on account of the overdose of foreign blood. We have injected as much as 7 c.c. without killing the animal, but there was severe shock and the result was negative.

#### The Disease in the Guinea-pig.

The disease in the guinea-pig is characterised by pyrexia, jaundice, prostration in varying degree, and hemorrhages in the skin, and in nearly all cases where the disease is allowed to take its course a fatal termination. It will be convenient to consider the findings under separate headings.

*Incubation period.*—The incubation period in guinea-pigs infected with blood from the patient varies within wide limits, and would appear to bear some relationship to the numbers and virulence of the spirochaete in the blood, and possibly also to the presence of immune substances in the blood. The relationship, however, is not always easy to follow, and apparently contradictory results are often obtained. Tables I., II., and III. show the average number of days from injection to death, in animals injected with blood taken on various days of the illness. It is necessary to note that the variation is almost entirely in the incubation period, the duration of the pyrexia being much more constant.

We have not included in the tables one guinea-pig which developed the disease 86 days after injection, although the animal was kept isolated throughout this period. This animal had been relegated to the stud as negative, and developed jaundice after becoming pregnant. Unfortunately, the identity of this animal was not established beyond all doubt, but from various corroborative evidence and the memory of the two men who cared for the animals there was every reason to believe that she was a guinea-pig which had been injected 86 days previously with human blood. The liver showed enormous numbers of spirochaete, many more than usual. The foetuses, about three-quarters term, were removed with the utmost precautions against contamination by maternal blood, and although no spirochaete or lesions typical of the disease could be found in the foetuses, an emulsion of the foetal livers produced the typical disease when injected into a new guinea-pig. The amniotic fluid

was clear and not bile-stained, and no spirochaetes could be found in the placenta, kidney, or lung (unfortunately the liver was lost) stained by Levaditi's method.

In passage animals the incubation period is much shorter and more constant, particularly after the third or fourth passage, and when very virulent strains are used the disease would seem to commence at times within a few hours of the injection of infected material.

*The pyrexia.*—The temperatures are taken morning and evening. As is well known, the temperature of a normal guinea-pig varies within wide limits, and is to some extent dependent on the external temperature. On this account it is often difficult to estimate the significance of a rise of temperature, but a little experience with guinea-pigs infected with this disease enables one to recognise, with few exceptions, the inception of the pyrexia which accompanies the infection. An important point is the comparison of the series of temperatures which are being recorded at the time. The temperature rises, sometimes with sharp spikes, often with only short steps, until the maximum is reached, and then falls sharply before death. The maximum temperature shows great individual variations, and one depends rather on the nature of the curve than on the absolute figure in recognising the pyrexia of infection. We insert four charts which are average examples. Two of these are animals infected from cases not showing jaundice and one is from a fatal jaundiced case. (Charts X.-XIII.)

CHART X.

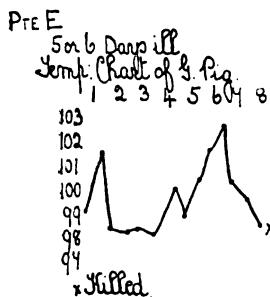

CHART X.—Animal infected from fatal case. (See Chart IX.) Spirochaete demonstrated in Levaditi preparations of liver and kidney.

CHART XI.—Animal infected from non-jaundiced case. (See Chart VII.) Spirochaete demonstrated in Levaditi preparations of liver and kidney.

CHART XII.—Animal infected from case with no jaundice. Spirochaete demonstrated in sections of liver and kidney (Levaditi).

CHART XIII.—Animal infected from case with jaundice. (See Chart II.) Spirochaete demonstrated in sections of liver and kidney (Levaditi).

In 24 guinea-pigs infected with human blood the average maximum temperature was 103° F., and in 53 animals infected with guinea-pig blood or liver (passage strains) it was 102.6° F. It may reach as high as 106° F. or more. The maximum once reached, the fall is very rapid, the downward curve on the chart being in the great majority of cases either a straight line or showing only one or two short steps. The temperature becomes subnormal and the animal dies within a few hours. This is generally 12 to 36 hours after the maximum temperature has been reached.

The duration of pyrexia from the beginning of the rise to the collapse stage is remarkably constant. In 17 of 22 animals infected with human blood this time is between three and four days, and the average for the series is 3.5 days. In passage animals the duration of pyrexia is somewhat shorter, averaging 2.7 days in a series of 38 animals. It is to be noted that with the majority of our infected guinea-pigs we have not waited for death, but have killed them to ensure having fresh material for injection, since in a few cases failure has followed injection of material from guinea-pigs which had died during the night. The animals are not killed until they are moribund, with a subnormal temperature and in a state of extreme collapse. Many animals, however, have been allowed to die, and we have never seen an animal live more than six hours after the stage at which we call them "moribund" was reached.

*Jaundice.*—Jaundice does not appear, as a rule, until the temperature reaches its maximum; that is to say, only a short time before the collapse stage sets in. It is first obvious on the prepuce or labia, then in the sclerotics, and rapidly increases till the skin becomes deeply yellow. In the passage animals, when death supervenes rapidly, the jaundice is never so marked as when the pyrexia period is more prolonged.

*Other symptoms.*—The guinea-pig becomes ill when the temperature begins to rise, but the indisposition becomes more marked as soon as jaundice appears. The fur becomes ruffed, the animal refuses to eat and becomes thin and pinched, and as the temperature falls collapse sets in, with extreme prostration. At this stage the action of the heart is

so weak that it is difficult to obtain blood from the ear veins for blood-counting purposes. Anaemia towards the end, when internal haemorrhages become more extensive, is extreme. A small number of observations would seem to indicate that there is a definite initial leucocytosis. A subsequent progressive fall in the leucocyte count was observed, but the question as to whether this was not more than accounted for by the anaemia has yet to be settled by more thorough investigation of its relation to the red blood cells and haemoglobin.

#### *Pathological Changes in the Guinea-pig.*

The post-mortem appearance in guinea-pigs which have died of the disease or which have been killed during the final collapse is very characteristic.

The skin is deeply and diffusely jaundiced, and jaundice is seen on all internal surfaces where the natural colour permits of its recognition. Numerous fine petechiae are seen in the skin of the flanks and groin, and in the muscle layers of the abdominal wall and subperitoneally. The loose reticular and fatty tissues of the groins and axilla show more extensive and diffuse patches of haemorrhage. Large haemorrhages sometimes occur in the loose retroperitoneal fatty tissue, so that the kidneys, particularly the left, may be more or less completely covered by a thin hemorrhagic layer. The small bowel usually, but not

CHART XI.

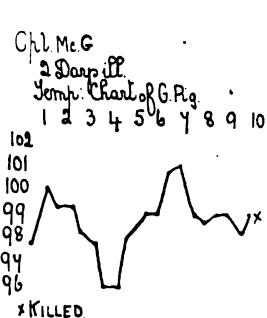

CHART XII.

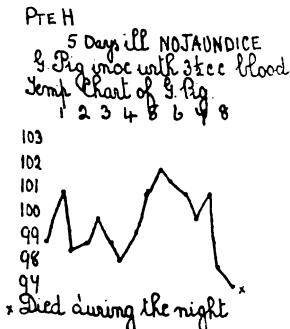

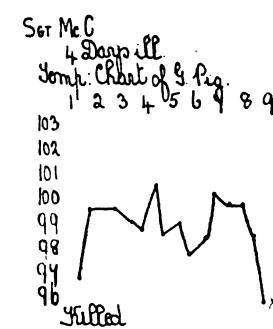

CHART XIII.

always, shows numerous superficial haemorrhages, usually in the form of circular or elliptical patches, 2 to 5 mm. in greatest diameter, and situate opposite the mesenteric attachment. A single injected vessel is seen leading to the patch on each side of the bowel, and the patch itself is often outlined by a fine rim of injected, anastomosing vessels. In animals killed in the early stages of the disease, however, the bowel haemorrhages are seen as minute pin-point spots situated at the side of the bowel at about the point where the encircling vessels commence to divide. These points evidently represent the commencement of the hemorrhagic patch. Hemorrhagic areas are also seen on the large bowel, and, in severe infections, on the stomach. In the latter situation they appear as groups of pin-point petechiae. Enlarged, injected, and often hemorrhagic lymph nodes are seen in the mesentery and in the groins.

The kidneys show very fine pin-point haemorrhages under the capsule and through the cortex on section. The adrenal glands are often seen with such large haemorrhages that all structure is obscure. The liver is more congested and of softer consistency than normal, but otherwise shows no gross changes. The spleen is congested, though not as a rule obviously enlarged. The lungs show the most characteristic gross change, being the seat of multiple, sharply defined haemorrhages of varying size, which contrast sharply with the white lung tissue, giving the striking appearance which the Japanese authors aptly describe as being "like the wings of a mottled butterfly." The haemorrhages vary from 1 mm. to 1 cm. in size, the larger ones being at the bases; when the haemorrhages are numerous they may be seen throughout the lung tissue, but when they are few they are often nearly all subpleural. They may form a strikingly symmetrical double row along the lateral margin of the lower lobe, one row on each side of the sharp margin.

The haemorrhages are an early occurrence in the infection. A guinea-pig killed exactly 24 hours after injection showed well developed lung haemorrhages and beginning bowel haemorrhages. It is to be noted, however, that the strain with which this animal was injected was at this time very

virulent, and a control animal died on the third day. Four or five other guinea-pigs killed at stages from 36 to 72 hours after injection have all showed definite haemorrhages.

#### *Microsopic Pathology.*

**The liver.**—The lesions seen in the guinea-pig's liver are essentially the same as those found in the two human livers—namely, uniform degeneration of liver parenchyma and an exudation of polymorphonuclear leucocytes, more extensive about the smaller bile-ducts. The degeneration varies greatly in degree, in some livers being very extensive, with considerable cell disintegration. As in the human liver, the leucocytes are found both diffusely between the liver column and in localised collections about the bile-ducts, particularly about the smallest ducts at their origin from the bile capillaries. They are also found within the bile-ducts much more commonly than in the human liver. It is to be noted that polymorphonuclear leucocytes are more numerous than normal in the blood, as seen in the vessels of all tissues. No structures which could be interpreted as dilated bile capillaries have been found in the guinea-pig liver; the quantity of bile pigment is much less in the human livers, only occasional cells showing pigment, but these often being packed with it.

After considerable study of both human and guinea-pig livers we are of the opinion that the jaundice is to be ascribed to the inflammatory process noted about the smallest bile-ducts, which probably produces a partial obstruction. If this be so, the condition must in strict terminology be called an obstructive jaundice, the result of a cholangitis or pericholangitis.

**Kidney.**—The lesions here, as in the human kidney, give the picture of an acute exudative nephritis with localised haemorrhages. The degeneration of the tubular epithelium may be very extensive, so that many tubules appear to be completely necrotic. The portions affected are, as in the human, the proximal convoluted tubules and the thicker portions of Henle's loops. Leucocytes occur in varying numbers. In severely affected kidneys they are numerous within and about affected tubules, and often immediately surrounding the glomerular capsule. Tubules are frequently seen distended with masses of leucocytes. Haemorrhages are more discrete than in the human kidneys examined, often being limited, apparently, to individual tubules, the blood lying within the tubule, and in smaller quantity between the coils. A tubule may be seen distended throughout its entire visible length with free blood and thrombus. Tubules are also to be seen distended with homogeneous albuminous exudate. Glomeruli are not markedly affected, although occasionally one may find the tuft pressed back by a mass of thrombus, or still more rarely of leucocytes.

**The lung.**—Under the microscope there are seen, in addition to the haemorrhages noted in the gross, numerous smaller ill-defined haemorrhagic areas. Thus haemorrhages involving only four or five alveoli may be seen. The larger haemorrhages are often limited by the boundaries of the lobule, but may be larger or smaller. They are characteristically pyramidal in section, the base lying against the pleura, which may be raised over a considerable area by a layer of free blood. The vessels leading to the haemorrhagic areas may sometimes be seen to be filled with leucocytes, or, again, a small mass of thrombus may be seen in the vessel, but the evidence is not sufficient definitely to indicate thrombosis as the cause of the haemorrhage. A considerable amount of cellular proliferation may be seen more evident in the alveoli bordering on the haemorrhagic areas. Thus alveoli may be seen packed with large cells of endothelial character. Leucocytes may be seen in small numbers among these cells, or more rarely an alveolus is found filled with leucocytes. The bronchioles show no epithelial changes, but may contain leucocytes and débris.

**The bowel.**—Only one bowel haemorrhage has been examined microscopically up to the present. In this case serial sections were cut through the entire haemorrhage. These show the haemorrhage to be associated with a large mass of lymphoid tissue, evidently, from its size and situation, a Peyer's patch. The haemorrhage surrounds this completely in the form of a fairly thin capsule of free blood and lies entirely within the submucosa. A small amount of free blood is also seen throughout the lymphoid tissue. Through the extended blood run widely distended capillaries, all apparently branches of the same arteriole and venule respectively—that is to say, in all the sections through the haemorrhage only one main arteriole and venule are seen to pierce the bowel wall, and that approximately opposite the centre of the haemorrhage.

**Mesentery.**—In one guinea-pig a small haemorrhage, 1 mm. in diameter, was observed in the mesentery close to the small bowel. This portion of the mesentery was mounted entire, and the haemorrhage was definitely seen to lie around the trunk of a small venule, the associated arteriole being quite free.

**Spleen.**—The spleen shows congestion and endothelial proliferation. The sinuses may be distended with large, clear, phagocytic cells containing red blood cells, leucocytes, or greenish-yellow pigment. Free pigment is also seen. These cells show not infrequent mitoses, and some show several irregular nuclei, or one giant nucleus irregularly lobed. Smaller spherical cells are also seen with a small, thin, crescentic nucleus at one border, the remainder of the cell being filled with packed red blood cells, or more commonly with eosinophilic granules. These cells resemble strongly the "eosinophiles" seen in lymph nodes from cases of Hodgkin's disease.

**Lymph nodes.**—The lymph nodes show congestion and some endothelial proliferation, as seen in the spleen, but, save where haemorrhages occur, no other significant change.

**Adrenal gland.**—In severe cases the adrenal is usually entirely haemorrhagic, the haemorrhage apparently originating in the medulla, and a certain amount of diffuse leucocytic exudation usually occurs.

#### *Spirochaete in the Guinea-pig Tissues.*

The liver of the infected guinea-pig killed at the state of collapse usually shows very large numbers of spirochaetes. They lie mostly along the borders of the liver cells, more commonly at the junction of two cells, or several organisms may surround the cell like a garland, the description which the Japanese workers give. We find them, however, frequently within the cells as well, although Inada and his collaborators say that this is rare, ascribing the fact to the absence of an immune substance in the blood of the guinea-pig. The spirochaetes, in some sections at least, are definitely more numerous at the periphery of the lobule and in the neighbourhood of the smaller bile-ducts. They may be also seen in small numbers in the connective tissue around these small bile-ducts, and not infrequently within the epithelial cells or free in the lumen of the smallest ducts.

In the kidney the distribution of the spirochaetes is characteristically in discrete areas, as noted in the human kidney, so that individual tubules or groups of two or three may show large numbers, the intervening tissue being free. The site is usually within the epithelial cells or free within the lumen of a proximal convoluted tubule close to its glomerulus. Often a mass of many spirochaetes may be seen lying among the granular débris at the centre of a regenerated tubule, and the impression gained is that multiplication has taken place in this situation. Spirochaetes may also be seen occasionally in the intertubular tissue. We have never seen spirochaetes in glomerular tuft or lumen.

We have found spirochaetes in the adrenal gland, lying within the epithelial cells of the capsule. We have also found them in the spleen (fairly numerous), lymph nodes, and in the heart muscle. We have never succeeded in demonstrating them in the lung.

In the blood of the guinea-pig they are fairly numerous, especially in the passage strains where one can find them in films in every third or fourth oil-immersion field. We have never seen them so numerous in the blood as would be expected from the description given by the Japanese authors, and we have not been able to find them with dark-ground illumination in the blood unless it was first haemolyzed with distilled water or saponin and then centrifuged.

The site of multiplication of the spirochaetes has not been determined, but from the numbers found in the liver it may be that it is in that organ that they grow. If multiplication takes place in the blood stream, a possible explanation of the numbers found in the liver, and around the proximal convoluted tubules in the kidney, is the relatively slower circulation at those points.

We have found that the older Levaditi process is the more reliable method of demonstrating the organisms in the tissues; on two occasions pieces of tissue prepared by the pyridin method did not show the organisms, while with the older method they were easily found. For films from the blood or liver we have found Fontana's method the most reliable and rapid, while with Giemsa the time taken for satisfactory staining is often 36 hours, and the organisms are not so distinctive or so easily found. With dark-ground illumination we have been disappointed, although the apparatus we use—a Leitz stage and a small arc lamp—shows *S. pallida* very well. With dark-ground illumination they are much less refractile than *S. pallida* or *S. refringens*. Their movements are slow and undulating, and the most characteristic movement is from side to side at one or both ends, a central portion remaining rigid. A slow spiral movement is occasionally seen. The spirochaetes show pronounced cross striation, caused, apparently, by a uniform series of refractile "beads" and suggesting the appearance seen in striated muscle.

The spirochæta as seen in the living condition or stained is of inconstant shape and has no fixed undulations. The thickness is about that of *S. pallida* or slightly less, and the length varies considerably, being on the average about the length of a specimen of *S. pallida* showing 12 to 14 turns. In films from liver or blood the spirochæta is often nearly straight or shows only wide undulations, while the ends in the majority of organisms are seen recurved like a fish-hook. There is a definite taper to each end from the central thicker portion. In the tissues prepared by Levaditi's method the spirochæta often show angular, irregular undulations, and the tapering at the ends is not so well seen.

We are greatly indebted to Dr. A. C. Coles (Bournemouth) for the photomicrographs which he has kindly taken for us and given us permission to use. They are taken by his special method and illustrate the appearance of the spirochæta in films very well. He has included specimens of *S. pallida* and *S. refringens* for comparison. The photographs of the organisms in the tissues have been done for us by Dr. J. T. Wigham (Trinity College, Dublin) and are also characteristic. We owe our best thanks to these helpers.

#### Technique of Passage.

In the passage of the disease from animal to animal the blood taken from the heart or an ground-up liver is generally successful. We have found, contrary to what Inada states, that the liver emulsion is more reliable than the heart's blood. On three occasions the liver has passed the infection where the blood failed.

The liver is crushed in a mortar and to about 10 gm. of liver is added 5 c.c. of saline, and the whole is briefly centrifuged to throw down particles which could block the needle. The supernatant fluid is then injected intraperitoneally, using about 2 c.c. for each animal.

The injection should be intraperitoneal to be satisfactory, since subcutaneous inoculations give a longer incubation period, and in two or three cases we have seen abscesses or spreading infection of the subcutaneous tissues at the site of subcutaneous injection. Passage has also been performed successfully by spreading liver emulsions on the shaved skin and by feeding the animal on carrot steeped in liver emulsions. We have also passed the infection with the urine of the killed animal. One attempt to infect with the bile failed.

#### Virulence.

The virulence of the spirochæta is very strikingly increased by passage.

The average period from injection to death in 23 animals

infected from human blood was 10 days. The average time

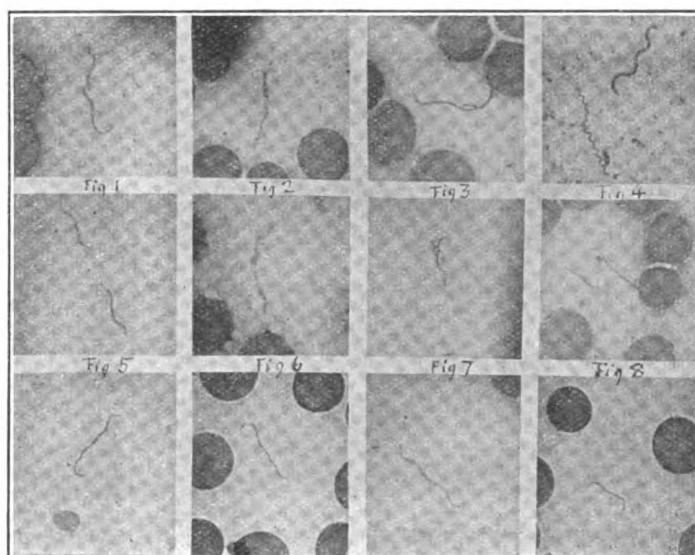

for death in 14 passages of one strain was 4·8 days, and of another strain, for 11 passages, was 5·3 days. This period for the first two or three passages may vary somewhat, but is usually 6 to 8 days; in succeeding passages it becomes progressively shorter and more constant, until a point is reached after 5 or 6 passages at which it becomes approximately fixed at 4 days. With small animals, when the strain is virulent, we have had them die on the third day, but this has always been in half-grown animals. In these young guinea-pigs the infection seemed to be overwhelming. The temperature reaction was slight and the jaundice not well developed. The duration of the pyrexia, as already mentioned, was definitely shorter in passage animals, and this becomes more marked in the later passages.

Jaundice does not have time to develop to the same extent as where the disease is of longer duration. Otherwise the post-mortem appearances show no important difference. The haemorrhages are often more extensive but this is not constant. Another criterion by which the increase in virulence may be judged is the number of spirochæta found in films from the blood and liver. In guinea-pigs dying from infection with human blood one may fail to find them in the blood films after 30 minutes' search of specimens stained by Fontana's method, while the liver films may show them only in 8 or 9 fields. In some animals infected from man we have only succeeded in finding the spirochæta in sections of tissues with Levaditi impregnation. In the animals of the latter passages it is always easy to find the spirochæta in the blood, although they are seldom numerous, but the livers of these animals show large numbers, 10 to 12 spirochæta in every oil-immersion field of a film made from the cut surface of the liver.

#### Experiments with Urine.

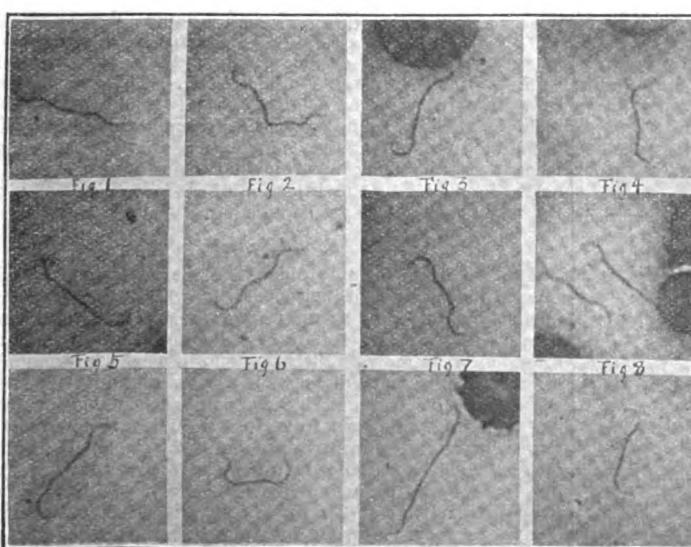

The Japanese authors showed that the spirochæta, both in the experimental disease and the disease in man, were excreted in the urine, the excretion commencing soon after the blood began to develop a demonstrable immunity and continuing in certain cases up to the fortieth day from the onset of illness. They were also able to infect animals with the urine of patients, 3 of 9 inoculations being positive when the injection was done before the tenth day, and 5 of 15 positive when the urine was taken between the eleventh and twenty-first days. They were able to find the spirochæta in the urine with dark ground illumination and regarded the excretion in the urine as a most dangerous source of infection. We have so far failed to find spirochæta in the urine and to infect animals with urine, although we have

#### PLATE I.

Shows 11 examples of *S. ictero-hæmorrhagica* in films of blood from infected guinea-pig. Multiplied 1000 diameters. Stained by Giemsa's stain. 1 example of *S. pallida* and *S. refringens* for comparison. Photomicrographs (I., II., and III.) by Dr. A. C. Coles, Bournemouth.

#### PLATE II.

*S. ictero-hæmorrhagica*.  $\times 1500$ . Various forms from blood of guinea-pig.

repeatedly searched for them and tried various methods of demonstrating them. It must be remembered that the patients were for the most part evacuated at the end of the pyrexial period, tenth to fifteenth day, and it is after this time that the spirochaetae become abundant. We are informed that the spirochaetae have been found with comparative ease at the base hospitals at a later period of the disease. In spite of this we think that our failure to get positive results at the earlier stage of the disease is of some significance, and think it is possibly due to the comparatively benign type of Weil's disease prevalent in this country. We have only in a few cases been able to examine the urine as late as the fifteenth day. We append a list of the experiments.

The animals were inoculated intraperitoneally with the centrifuged deposit from the amount of urine mentioned. They were inoculated with the urine of the same patient on two successive days, and were watched and had their charts kept for 14 days.

G.p. 21	...	...	150 c.c. on 14th and 15th day of illness (Pte. G.)
"	22	...	300 " 10th " 11th " (Pte. H.)
"	23	...	150 " 13th " 14th " (Pte. C.)
"	24	...	150 " 15th " 16th " (Pte. MacD.)
"	43	...	170 " 13th day of illness (Pte. L.)
"	52	...	320 " 13th and 14th day of illness (Pte. B.)
"	64	...	320 " 7th " 8th " (Pte. C.)
"	67	...	300 " 7th " 8th " (Pte. T.)
"	74	...	300 " 6th " 7th " (Gnr. W.)
"	87	...	200 " 11th day of illness (Pte. B.)

The results were consistently negative. In one of the fatal cases there was suppression of urine for 24 hours before death, and we were unable to secure a specimen to inoculate an animal. In the second fatal case which we were able to investigate there were not sufficient animals available at the time to try to infect with the urine.

#### Immunity.

In their first paper on infective jaundice the Japanese authors showed that the blood of convalescent patients contained substances capable of curing infected animals and of protecting them against infection; they dated the appearance of this immune substance at about the tenth day of illness, at which time it first became demonstrable. which we have been allowed to see through the kindness of Dr. Flexner, director of the Rockefeller Institute, they report that they have succeeded in immunising a horse and in using the serum therapeutically with encouraging results. The following experiments were done in confirmation of the original Japanese paper:-

*Experiment 1.*-Guinea-pig 35. The animal developed jaundice eight days after injection, the temperature being on the downward grade after reaching 103° F. The animal was then injected with 2½ c.c. of serum from a patient on the fourteenth day of illness. It showed immediate improvement and began to feed, and the fur became normal; all jaundice was gone on the eleventh day. On the fourteenth day 2 c.c. of liver emulsion rich in spirochaetae was administered and did not infect the animal. This injection was repeated on two subsequent occasions with virulent strains and the animal remained immune.

*Experiment 2.*-Guinea-pig 40. The animal was injected at the same time with 2½ c.c. of serum from a convalescent patient, and 1 c.c. of liver emulsion with 1 c.c. of heart's blood from an animal which had died of jaundice. No symptoms developed for 14 days. A control animal died in 7 days. Guinea-pig 40, reinoculated on the fifteenth day, died four days later with jaundice and typical signs. This would indicate that passive immunity is transient, and that

although the animal was protected by the immune serum, it did not develop any active immunity, since infection had not occurred.

*Experiment 3.*-Guinea-pigs 41 and 47 were subjected to a repetition of Experiment 1, and the result was identical.

*Experiment 4.*-Guinea-pigs 45 and 46 were treated with immune and normal serum respectively when the collapse stage had been reached. Both died within three hours.

*Experiment 5.*-Guinea-pigs 83, 85, 86, 89, and 90 were each injected with the same quantity of virulent liver emulsion, and at the same time human serum was administered as follows:-

Guinea-pig 85.-3½ c.c. normal human serum.

Guinea-pig 83.-2½ c.c. serum from jaundice case taken on sixth day of illness.

Guinea-pig 89.-2½ c.c. of serum from same case taken on eighth day.

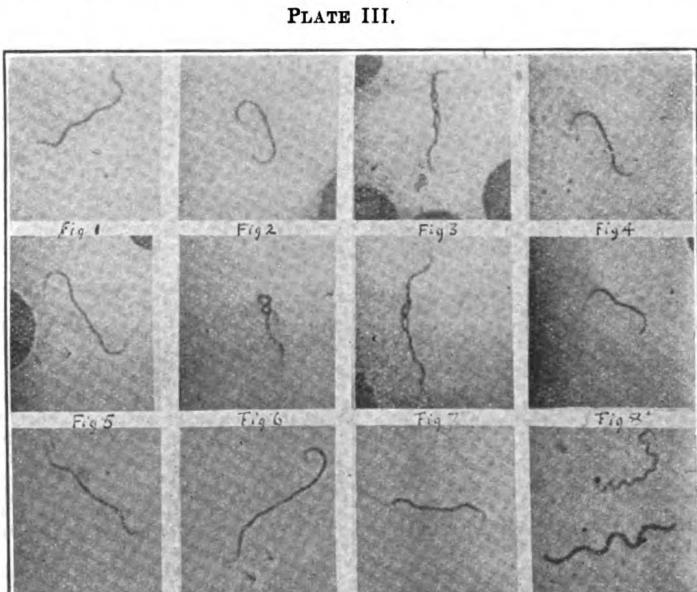

Guinea-pig 86.-2½ c.c. of serum from same case taken on tenth day.

Guinea-pig 90.-2½ c.c. of serum taken from same case on twelfth day.

Guinea-pigs 85 and 83 died on the fifth day with typical signs of the disease. Guinea-pig 89 died immediately after injection. Guinea-pigs 86 and 90 developed no symptoms.

In only one respect do the results of these experiments differ from those obtained by Inada and his assistants, who state that the serum must be given before the appearance of the jaundice in order to cure the animal. We have found that the serum of a convalescent patient will cure the animal even after the appearance of jaundice, if it be given before the collapse stage is reached.

After these experiments had been done we suggested the immunisation of a horse with a view to treatment, but the suggestion was not put into practice, partly owing to the fact that the prevalent type of the disease was relatively benign and did not seem to call for very active treatment. The Japanese workers, in their treatment with serum, succeeded in considerably lowering the death-rate, which was high (32 percent.), but did not shorten the duration of jaundice. They also were apparently able to rid the circulating blood of spirochaetae and to hasten the appearance of the immune reaction in the blood. They found that rather large doses of the horse serum were

Shows examples of *S. ictero-haemorrhagica* in blood films. Nos. 2 and 3 on this plate are *S. ictero-haemorrhagica* from human blood, Corp. MacG. (see Charts VII. and II.). Magnification 1500 diameters. Stained by Geimsa's stain.

In the later paper, the proofs of which we have been allowed to see through the kindness of Dr. Flexner, director of the Rockefeller Institute, they report that they have succeeded in immunising a horse and in using the serum therapeutically with encouraging results.

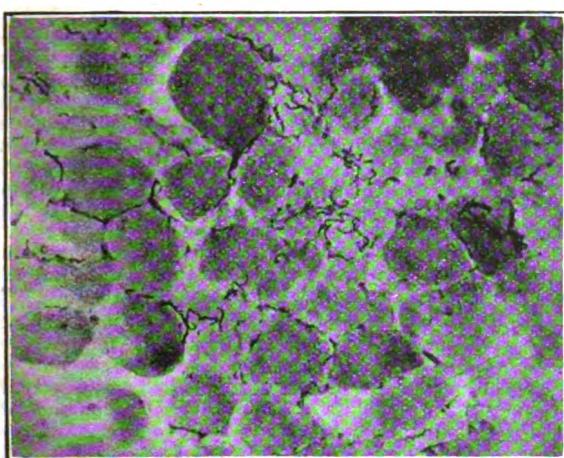

The following experiments were done in confirmation of the original Japanese paper:-

necessary, 60 c.c. or more, and that better results were attained by early administration. This would indicate that a very high titre serum would give better results. They found that the serum which they had prepared was about as potent as that of a convalescent case. They have further attempted to produce active immunity by the injection of carbolised cultures, but the results are not as yet convincing.

#### Sero-diagnosis.

As soon as it became clear that there were considerable numbers of cases of spirochaetosis which did not show obvious jaundice, it seemed to us desirable to find some convenient form of laboratory diagnosis other than the infection of animals. With this end in view a large number of experiments were done with a view of finding whether this could be attained by a complement-deviation test. Antigens were prepared in various ways from the livers of guinea-pigs with very great numbers of spirochaetae, but no test sufficiently reliable could be elaborated. There was nearly always a difference in the haemolysis which held out hopes of arriving at a reliable test, but there was not sufficient constancy. For one instance immune guinea-pigs did not give a positive reaction as compared with normal

animals. A further point was that the bile, both in the serum and in the antigen, produced strong anti-complementary action.

#### Cultures.

Inada and Ito succeeded in cultivating the spirochaetae in 1915, and state that they got their original cultures by Noguchi's method.

Ito and his collaborators publish a fuller account of the cultivation of the organism in the *Journal of Experimental Medicine* for April, 1916, and have had no difficulty in cultivating the spirochaetae by taking the heart's blood of an infected animal and growing the blood in deep blood agar or blood gelatin tubes. They state that the cultures begin to grow in 8 days, the maximum being reached in 16 to 20 days. So far as we are concerned, we have been unable to obtain cultures, although we have attempted it repeatedly in different ways and at different temperatures. We tried the original Noguchi technique with guinea-pig liver and kidney as the tissue component, with blood, ascitic fluid, or guinea-pig blood as the enriching medium, and with agar or broth as the basis; in all cases the results were negative. We have tried different infecting agents, blood, liver, or kidney from animals with jaundice, and never succeeded in getting an undoubted culture. Though we have often thought that we could demonstrate the spirochaetae by staining with Fontana's method, we could not see them in such cultures with the dark-ground stage, while, conversely, on one occasion we thought that we had them in culture after examining by the dark-ground stage, but were unable to stain the organism. We attempted several times to cultivate direct from the patient, taking early cases and a relatively large amount of blood into deep agar tubes and covering with paraffin, but these efforts were also abortive.

We mention these negative results as showing that cultivation is not so simple a task as might be supposed from the literature. The possibility of an inherent difference in the organisms is to be considered.

#### Experiments with Lice.

When we began to consider the route of infection in the soldier our first idea was the possibility of lice being the infecting agent, as they may be said to be invariably present on soldiers serving in the field. Some colour was lent to this idea by the fact that we had never seen an officer with true infectious jaundice. The Japanese authors had considered the possibility of fleas and mo-quitos being the intermediate host and discarded both. The fact that the majority of cases came from a relatively small area, that jaundice was rare except in one part of the line, as will be more fully explained later, and that divisions which left the infected area did not have any more cases of jaundice suggested that lice were not responsible. On the other hand, the analogy of relapsing fever made it necessary to attempt some experiments on the matter. The lice seldom survived three days' separation from the human host and seemed not to thrive on guinea-pig blood.

Guinea-pig 88.—40 lice were fed on an animal which had spirochaetae in the blood-stream, demonstrated by films; on the next day the survivors were fed on a fresh animal (Guinea-pig 88), and again on the following day the survivors were fed on this same animal. Result negative.

Guinea-pig 97 and 93.—The same as above.

Guinea-pig 122.—50 lice were allowed to feed on a patient on the fifth day of his illness, and were then fed alternately on the patient and the animal till there were no survivors at the end of 60 hours. Result negative.

Guinea-pig 124.—The same experiment with another patient on the fourth day of illness.

Guinea-pig 123.—100 lice were taken from the clothing of a patient on the sixth day of illness, crushed and emulsified in saline, and injected into the peritoneal cavity of the animal. Result negative.

Guinea-pig 129.—Same experiment as the last with 40 lice. Result negative.

Guinea-pig 125.—Lice taken from the clothing of a patient on the ninth day of illness were fed on the animal till there were no survivors. Result negative.

There is an obvious fallacy in these experiments which is hard to eliminate. The incubation period in the louse may be prolonged and the parasite not become infective for several days, the lice dying, when kept in captivity, before the infective period is reached. Further, the lice taken from a man may not have fed on him while the spirochaetae were abundant in the blood-stream. The experiments, however, so far as they go, bear out what would have been expected from the almost strict area from which the cases came. A large number of lice have also been examined by Sergeant Peacock, R.A.M.C., by staining

methods with a view of finding the spirochaetae. The lice were either taken from men with jaundice or deliberately infected from animals with spirochaetae demonstrable in their blood, and all the examinations were negative.

From every point of view we think that it is improbable that lice are the intermediate hosts if there be an intermediate host in the cycle of infection. We have tried no experiments with mosquitoes, and though the incidence went up as the warm weather set in and has declined with the colder weather, when mosquitoes are scarce, it is not sufficient evidence to incriminate these insects. There were, however, undoubtedly cases during last winter. The restriction within narrow limits of the epidemic is also in opposition to the hypothesis of transmission by the mosquito.

#### Epidemiology.

There were, as we are informed, undoubted cases of Weil's disease during the winter of 1915-1916 which were seen at the base hospitals, but the diagnosis was not confirmed by animal inoculation. So far as we know, the first cases which were recognised in this area occurred at the end of April and the beginning of May, 1916. The number of cases varied from time to time. There were more cases seen during the early part of July and the end of August than at any other periods, though there were a few cases passing through during the whole summer. At one time there were 15 cases under observation, and others had been evacuated on admission as sufficiently well to travel. The incidence seemed to vary with the weather conditions. Thus during and immediately after a dry, warm spell of summer weather there were very few cases, but with the advent of rainy weather the incidence went up and many cases were admitted. On two occasions this occurred, the most striking being after the dry spell which prevailed during the end of July and the first fortnight of August. From August 1st to the 23rd there were no cases of jaundice, and from August 23rd to Sept. 1st 12 cases were admitted. Rain fell in considerable quantities from August 13th to the end of the month.

We know of only one officer who definitely developed Weil's disease, all the cases having occurred among the other ranks and practically always among the "trench troops." The men always either developed the disease in the front line or very soon after they had been relieved. Certain divisions in a corps were affected, others being free. Within the divisions certain brigades were affected, and within the brigades certain regiments had more cases than others. We found that a regiment which had a number of cases while in the line was not infected while in rest billets, but again produced cases when it returned to the trenches. There were certain areas from which cases came, and if we represent the line from which we collect as a straight line divided into six segments, numbered from left to right, Segment 1 and Segment 4 provided the great majority of cases.

1	2	3	4	5	6
---	---	---	---	---	---

By the kindness of Colonel Gerrard, A.M.S., we were allowed to see a "spot map" of Sector 1, which had been kept for about two months, the map representing the cases as they occurred among the troops in occupation of the area, and giving the place where the affected men had been on duty. This map showed that the cases in the infected area were grouped round two small sections of trench, one at each end of Sector 1.

A new division, which had, up to the time of taking over the infected area, never had a case of jaundice, developed cases of jaundice within 14 days of going into the new trenches, and the same division, after being relieved and going to a new part of the line, was again free from cases. Again a new division took over the infected area, and in the same way cases of jaundice cropped up within a short time.

The trenches in this infected area were wet, not well drained owing to the nature of the ground, and in some places, even in dry weather, never properly dried. This was so in both the segments of the line from which cases came. This is suggestive when one remembers that Inada and his collaborators state that cases of jaundice occurred in the wet shafts of a mine, and that the men working on the surface and in the dry shafts were not infected, and, further, that

when these wet shafts were pumped out on their advice the incidence markedly decreased. They also suggested that possibly the entry of the organisms might be through the skin—a guinea-pig can be infected through the skin—but they were of the opinion, after a general review, that the mode of entry was through the alimentary canal. A point of interest is, though it is complicated by the contemporary onset of colder weather, that the incidence of the disease in our area had practically ceased, and that the troops were issued with high "gum" boots a week before we saw the last case of jaundice. Since writing the last sentence two cases have been noted.

In the proofs of a forthcoming paper by the Japanese workers which was sent to us by Dr. Flexner it is stated that they have succeeded in finding the spirochaetae of jaundice in the kidneys and urine of 38 per cent. of ordinary field-rats in the infected areas in Japan. They suggest that the infection may be conveyed by the rats' urine, either directly or indirectly. We have not yet had time to confirm these findings, but hope soon to be able to do so.

Cases have occurred in the Allied troops in different parts of the front. Dr. L. Martin has published an account of some cases investigated by him in the French Army, and we also know of other cases which have occurred among the troops in Flanders which have also been proved experimentally. Whatever be the portal of entry of the spirochaeta it would appear that wet and muddy trenches are a predisposing factor. If the infection had been water-borne there would have been a more widespread epidemic. If vermin or mosquitoes had been the infecting agents the epidemic could hardly have been so localized, and the experiments which we have performed, such as they are, would seem to exonerate them. We would also add that there have been up to now no ward or laboratory infections. The patients have been cared for in a general ward with no further precautions than would be carried out if they were enteric cases.

#### Conclusion.

The clinical and experimental examination of about 100 cases of Weil's disease which we have been in a position to investigate during the last six months justifies, we think, the conclusion that the disease, as it has been observed among British troops in Flanders, is identical with that described by Inada and his collaborators in Japan.

The virulence of the infection in the cases seen here is much less than that described in Japan, which is well shown by the comparatively low mortality. All the essential findings of the Japanese authors have been confirmed, save that our cultural attempts have so far failed.

In addition we have noted the occurrence of cases of spirochaetosis which have not shown any external jaundice.

The success of our work is to a great extent due to the efficiency and zeal of our laboratory attendant, Sergeant B. Baker, R.A.M.C. (T.F.).

*After-note.*—Since writing the paper we have been able to confirm the statement of the Japanese workers mentioned in the paper with regard to the finding of the spirochaetae in the kidneys of field-rats. Of 9 rats taken from the right part of Segment 1 in the chart in the paper, 5 proved infective to guinea-pigs. Of 6 rats from the left end of Segment 1 one communicated the disease. The kidney of the rat was crushed and emulsified, and injected intraperitoneally into the guinea pig. The disease in the infected animal was typical, and we have found the typical *S. inter hemorrhagia* in the organs of the guinea-pig. Levaditi preparations of the rat kidney have shown the spirochaetae, and we have also found them in films made from an emulsion of the kidney stained by Fontana's stain.

**MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.**—The usual monthly meeting of the committee was held at 300, High Holborn, on Jan. 19th, Dr. F. J. Allan being in the chair. The reports submitted showed the epidemic of influenza which has been universal throughout the country to have affected the medical profession. It was decided to apply for a further £15,000 in the new 5 per cent. War Loan, and to convert the society's existing holdings, amounting to £25,500, also in the new 5 per cent. War Loan. This transaction, when complete, will give the society a total of £40,500. The important question of the depreciation of stock values was considered and a further £600 added to the investment reserve, which now stands at £10,000.

## TOXIC JAUNDICE IN MUNITION WORKERS.<sup>1</sup>

BY MATTHEW J. STEWART, M.B., CH.B. GLASG.,  
M.R.C.P. LOND.,  
CAPTAIN, R.A.M.C. (T); PATHOLOGIST TO THE EAST LEEDS  
WAR HOSPITAL.

THE aspects of the subject dealt with in this contribution are: (I.) the morphological changes in the blood occurring in a series of 14 clinical cases of toxic jaundice from trinitrotoluene poisoning; and (II.) certain points in the morbid anatomy of the disease as observed in a series of seven fatal cases.

#### I.—Changes in the Blood.

The 14 cases here recorded are those of munition workers who were admitted to hospital during the months August to December, 1916. Most of them have been under observation for weeks or months, and as many of them are still coming up regularly for examination these results must be regarded as partial and preliminary. Sufficient has already been made out, however, to show that very profound changes in the composition of the blood may occur as a result of trinitrotoluene poisoning; indeed, it might be said that such changes are the rule in cases where pronounced clinical symptoms, and especially jaundice, have manifested themselves. One case only out of the 14 examined, a man who, clinically, was never seriously ill, showed no blood changes. All the others had definite deviations from the normal of some sort or another.

*A. Changes in the leucocytes.*—These were worked out on a basis of the absolute number per cubic millimetre of each variety of leucocyte, and the following fairly elastic figures were taken as the limits of the normal:—

Neutrophil polymorphs	... 3600-6750	per c.mm.
Lymphocytes	... 1200-2700	"
Eosinophils	... 30-360	"

The leucocytic changes as calculated on this basis may be given as: (a) Neutrophil leucopenia, (b) neutrophil leucocytosis, (c) lymphocytosis, and (d) eosinophilia.

(a) *Neutrophil leucopenia.*—This, the most striking of the leucocytic changes, was present at some stage of the disease in 9 out of 14 cases (Nos. 1, 2, 4, 8, 9, 10, 12, 13, and 14). In 4 of these (Nos. 1, 2, 10, and 12), 2 of them fatal, the leucopenia was extreme, under 1100 per c.m.m.; of the other 5 affected, the highest neutrophil count was 3175. In the 2 fatal cases (Nos. 1 and 2) the leucopenia was progressive and terminal, the final counts being 120 and 636 respectively. One case (No. 10) illustrates very well the polymorpho-nuclear recovery which accompanied clinical improvement in the condition of the patient. While the patient was seriously ill the neutrophils numbered only 1080 and 1092. A fortnight after his discharge from hospital they were 6280. In 3 cases (Nos. 2, 8, and 10), one of them fatal (No. 2), neutrophil leucopenia was associated with an anaemia of pernicious type (*vide inf. a*).

A progressive failure of the leucoblastic function of the bone marrow is therefore to be regarded as one of the most common manifestations of severe trinitrotoluene poisoning, but that it is not a constant feature in fatal cases is shown by Case 3, details of which are given below. It may be mentioned also that in another fatal case, which was not investigated during life, the bone marrow showed evidence of great leucoblastic, as well as erythroblastic, activity. Here the whole duration of illness was only one month, yet the liver changes were extreme, and it seems reasonable to suppose that there had not been time for the development of the full toxic action on the marrow. Whether this neutrophilic failure is due to a direct action of the poison on the leucoblastic tissue one cannot say with certainty, inasmuch as all the cases in which it occurred presented clinical evidence of an antecedent or accompanying hepatic lesion (jaundice, &c.), while both the fatal cases showed a typical advanced trinitrotoluene cirrhosis of the liver post mortem.

(b) *Neutrophil leucocytosis.*—This change was present in a notable degree in one ('at') case only (No. 3). Here, at the first examination, the total leucocyte count was 14,200,

<sup>1</sup> A contribution to the discussion on the subject at the Royal Society of Medicine on Tuesday, Jan. 23rd.

of which 10,000, or 70·5 per cent., were polymorphonuclears, while a month later, on the day before the patient's death, the figures were 22,000 and 19,200 (87·25 per cent.) respectively. This change was unassociated with any variation in the lymphocytes or in the red cells or haemoglobin, but at the first count there was an eosinophilia of 1000 per c.mm. Post-mortem examination showed the bone marrow in the shaft of the femur to be largely fatty, with a narrow peripheral zone of red. Microscopically there were found small foci of very active leucoblastic proliferation. The inspection,

*Table giving a Summary of Blood Changes in 14 Cases of Trinitrotoluene Poisoning.*

Case.	Age.	Lymphocy-tosis.	Polymorpho-nuclear.		Anaemia of pernicious type.	Eosinophilia.

\* Male.

however, failed to reveal any inflammatory cause for the persistent leucocytosis, which stands out in striking contrast to the other fatal and clinically serious cases. In three other cases (Nos. 1, 9, and 13) an early and slight neutrophilia was present, but was speedily followed in each instance by a pronounced leucopenia.

(c) *Lymphocytosis.*—This was one of the most commonly observed changes; it occurred at some time or other in 9 out of 14 cases (Nos. 2, 4, 5, 6, 7, 8, 9, 10, and 13), and varied in different patients from 3150 to 5100 per c.m.m. Considerable variations were often seen from time to time in the same patient, but the fluctuations were irregular and did not appear to have much, if any, significance. In the remaining 5 cases the lymphocytes ranged within normal limits, except that in two cases (Nos. 8 and 10) there was a single temporary drop to 1040 and 1160 respectively. The chief point to be observed is that even in fatal cases and in those showing profound polymorphonuclear or erythrocytic failure the lymphocytes were maintained at or above the normal level. In two cases a lymphocytosis was the only change noted.

(d) *Eosinophilia.*—This was observed in three cases (Nos. 3, 5, and 13), and in two of these it was well marked, once (No. 3) accompanying a marked neutrophil leucocytosis, once (No. 13) with a slight neutrophilia. It appears to be of doubtful significance, but it may be noted that in no case did an excess of eosinophils coexist with a neutrophil leucopenia. Altogether the number of eosinophils was found to be a very variable quantity in these cases.

B. *Changes in the erythrocytes and haemoglobin.*—These have been much less conspicuous than the leucocytic changes. A serious degree of anaemia was observed in 3 cases only, all the others, including 2 of the fatal cases, had red cell counts of over 4,000,000, but a slight grade of chlorotic anaemia was present in several. In the 3 serious cases the anaemia was of the "pernicious" type, with a colour index over 1, but very varying degrees of severity were presented. In the most extreme case there was a fall in the red cells to well under 1,000,000, and as the haemoglobin was not reduced to anything like the same extent (25-30 per cent.) a high colour index (1·5 to 1·8)

presented itself. The erythrocytes in this case were greatly altered qualitatively, anisocytosis was well marked, with many megalocytes. During the worst phase numerous erythroblasts made their appearance, and polychromatophilia was present. In the other 2 cases the red cells fell to 1,500,000 and 2,900,000 respectively, with colour indices of 1·4 and 1·1. Qualitative changes in the red cells were not striking, some anisocytosis with many megalocytes, and in one case slight polychromatophilia. It is to be noted that punctate basophilia was not seen in any case, which is in striking contrast to the findings of Malden in workers in dinitrobenzene and anilin.

## II.—Some Points in the Morbid Anatomy.

One of the chief problems here is the nature of the liver changes. The lesion appears to lie somewhere between a subacute yellow atrophy and an ordinary multilobular cirrhosis of irregular distribution. The action of the poison on the hepatic cells is probably slow and insidious, and the degenerative changes are speedily followed, if not actually accompanied, by leucocytic infiltration and fibroblastic overgrowth. The degenerative and other processes, once set going, are progressive, even when the patient has been removed from the influence of the poison, and in a certain proportion of cases a fatal termination ensues in from 4 to 12 weeks after the first symptoms. Certain portions of liver tissue escape complete destruction, and these show evidence of more or less regenerative hyperplasia. It may be assumed that in some cases this persistent and regenerated hepatic tissue will be sufficient to maintain the life of the individual for a considerably longer period than three months, but what the ultimate fate of such persons will be time alone can show. The after-history of surviving cases of trinitrotoluene poisoning will require to be carefully investigated, not only on account of their great intrinsic interest, but also for the light they may throw on cirrhosis of the liver in general.

I have recently had the opportunity of examining, post mortem, 12 cases of accidental death in workers at a munition factory. In one of these, a woman aged 38, distinct liver changes were discovered—namely, an early but definite round-cell infiltration of the portal tracts and numerous discrete (?) regenerative nodules of varying size scattered throughout the organ.

With regard to the series of 7 post-mortem examinations on which these remarks are based a few points of outstanding interest may briefly be referred to.

The weight of the liver varied from 20 to 32 ounces, the average being 27 ounces. The degenerative cirrhotic process, as evidenced by the dark-red contracted areas, was always most advanced in the left lobe and inferior marginal region of the right lobe. Often these two portions of the organ were composed almost entirely of red tissue. Another striking feature was the frequency with which large rounded yellow nodules projected from the under surface of the right lobe on each side of the gall-bladder, less often from the Spigelian and quadrate lobes.

The bone marrow of the femur was examined in 6 cases. In 5 of these the red marrow was in excess, extending well down the shaft of the bone, but on microscopic examination a definitely erythroblastic reaction was found in one case only. Here the yellow marrow of the shaft was completely replaced by a cellular red marrow, the appearance being comparable to that seen in pernicious anaemia. Evidence of considerable leucoblastic activity was also present. Unfortunately, there had been no opportunity to examine the blood during life. In Case 3, the patient with neutrophil leucocytosis, the shaft marrow was fatty, with a narrow red layer next to the bone. Microscopically some small foci of active leucoblastic proliferation were seen.

The spleen was never appreciably enlarged, the weight varying from 4 to 7 ounces in different cases.

Aëtates to the extent of five or six pints was present in 3 cases. Clinical examination of the fluid in one case showed a very scanty cellular deposit with a preponderance of leucocytes. A very few red blood corpuscles and endothelial cells were also present.

Haemorrhages in various situations were present in 5 cases, most frequently in the peritoneum and pericardium, less frequently in the stomach, lungs, pleura, endocardium, and skin. In one case there was very extensive haemorrhage into the peritoneum and subperitoneal cellular tissue, especially

of the omenta, mesocolon, mesentery, and appendices epiploicae. In the same case there was profuse terminal oozing into the stomach. In the other 4 cases the haemorrhages were mainly petechial.

Perhaps the most interesting single case was that of a man, aged 52, where the lesions of trinitrotoluene poisoning were associated with a well-marked haemochromatosis affecting especially the liver, pancreas, and abdominal lymph glands. Unfortunately, the urine had not been examined during life, and at the post-mortem examination the bladder was empty. The haemosiderin granules, which gave a bright blue colour when treated with potassium ferrocyanide and hot hydrochloric acid, but a green colour with cold hydrochloric, were most abundant in the lymph glands. It is fairly certain that we are here dealing with two independent affections, inasmuch as it has been shown that a very long time, a year or more, is required for the deposition of such large amounts of iron-containing pigment, while the illness due to trinitrotoluene was in this man's case only of 10 weeks' duration. It is possible, however, that the pre-existing hepatic lesion may have made that organ unduly susceptible to the action of the poison.

Leeds.

## Reviews and Notices of Books.

### Gynecology.

By WILLIAM P. GRAVES, A.B., M.D., Professor of Gynecology at Harvard Medical School. With 303 half-tone and pen drawings by the Author and 122 microscopic drawings by MARGARET CONOREE and RUTH HESTIS; 66 of the illustrations in colours. London and Philadelphia: W. B. Saunders Company. 1916. Pp. 777. Price 30s.

THIS is designed both as a text-book and a general reference work. It is divided into three parts; the first deals with the physiology of the pelvic organs and the relation of gynaecology to the general organism, the second is intended primarily for the undergraduate and deals with gynaecological diseases, and the third is devoted exclusively to the technique of gynaecological surgery, and is written for the assistance of the advanced student and practitioner. The section dealing with the relationship of gynaecology to the general organism forms a most interesting and instructive review of our knowledge on these points and will prove extremely useful to the student in view of the increasing importance at the present time of the internal secreting glands. It includes an account of hypo-function of the ovaries and its relation to infantilism and a useful résumé of Schickèle and Keller's views on chronic metritis and cystic degeneration of the ovaries and their relation to uterine haemorrhage. Our knowledge, scanty as it is, of the relations to gynaecological diseases of the thyroid, the parathyroid, the adrenals, and the hypophysis is also excellently summarised. As the author points out, the subject is a comparatively new one, and he is anxious to impress upon the student the importance of the correlation of all the branches of medicine and surgery. The completeness with which the author treats these subjects is exemplified by the fact that he includes in his review such conditions as the nervous system, the peritoneum and omentum, the bones and joints, the gall-bladder, and the acute infectious diseases.

Part II. contains a very good account of the common gynaecological affections. We notice that the author does not distinguish between kraurosis and leucoplakia vulva, and the statement that the main symptom of kraurosis is itching is not quite correct. Professor Graves correctly points out that the subject of endometritis is in a state of considerable confusion, yet he does not do much to simplify matters, as he still describes gland hypertrophy resulting from circulatory changes under the heading of endometritis. The section on cystitis and pyelitis is good. There is an interesting description of the radiation treatment of cancer and of Percy's heat treatment. The excellent results obtained by Howard Kelly in the treatment of fibroid tumours by radium are also alluded to—a mode of treatment of much promise for the future. It is surprising to find in so excellent a book a recommendation of the use of intra-uterine pessaries in the treatment of anteflexion of the uterus.

In the section dealing with the amenorrhoea of youth, Professor Graves also quotes Rieck's treatment of amenorrhoea and oligomenorrhoea by the intra-uterine stem pessary only to condemn it. Would it not have been better to have omitted it altogether?

The various gynaecological operations are well and clearly described in Part III., and the value of the book is greatly enhanced by the very numerous and good illustrations, mainly drawn by the author himself. The drawings of the microscopic sections are also good, and the index is a complete one.

### Raymond, or Life and Death.

By Sir OLIVER J. LODGE. London: Methuen and Co., Limited. 1916. Pp. 404. Price 10s. 6d. net.

MORE than three years ago, in his presidential address before the British Association, Sir Oliver Lodge stated his conviction that memory and affection are not limited to that association with matter by which alone they can manifest themselves here and now, and that—as a corollary of this persistence—personality itself persists beyond bodily death. He had been led to this conclusion, not by such things as intuition and revelation, but by the careful and systematic examination of occurrences still regarded as occult, and by the reduction of these to order through the methods of science. The book before us records a further examination of the evidence for the survival of personality in a particular case, and as the case is the writer's youngest son, who met his death during the attack on Hooge Hill in September, 1915, it has a special and poignant interest.

Sir Oliver Lodge deals with his subject in three parts. The first, described as the "Normal Portion," gives a short biographical sketch of Raymond Lodge as he was in life, with his letters from the front and others from brother officers about him. The second part is entitled "Supernormal Portion," and deals with the messages received from Raymond Lodge after his death—"communications," as the author describes them, "from which sentiment is not excluded, though still they appear to be guided and managed with intelligent and on the whole evidential purpose." In the third part, with the heading "Life and Death," the author defines the part which he takes in the great controversy and his view of "the real existence of some kind of vital essence or vivifying principle as a controlling and guiding entity."

With the first and third parts criticism has little place. For the intimate glimpse into a strenuous young life lamentably cut short nothing but gratitude can be felt, and this part alone makes the book worth reading. The equally intimate glimpse into the author's own philosophy—the result of a lifetime of steady patient work and thought—is a second gift of no mean value. The value of the "communications" is much more difficult to appraise. The obvious criticism must indeed arise in every mind: how trivial and indeed almost contemptible are the communications themselves. And the author has done well to devote a chapter to precisely this criticism, explaining that the demand for a proof of the identity of a departed friend is best achieved by the recalling of trifling reminiscences. Affection and lofty sentiment must be the common attributes of the spirit world, but particular little jokes and morsels of fun give away the identity of the "communicator." Let us grant this as reasonable, and let us accept the possibility of communications by this means through a sensitive control, we believe, for our part, that intercourse between spirit and spirit, when any occurs, occurs without the medium of a control. Sir Oliver Lodge appears to have reached by a system of wiring and motor-transformers what may conceivably be freely accessible in wireless telegraphy—if such a simile can be justified.

### LIBRARY TABLE.

*Text-book of Nervous Diseases for the Use of Students and Practitioners of Medicine.* By CHARLES L. DANA, A.M., M.D., LL.D., Professor of Nervous Diseases in Cornell University Medical College. Eighth edition. Bristol: John Wright and Sons. 1916. Pp. 632. Price 21s. net.—Dr. C. L. Dana's well-known text-book of nervous diseases has reached an eighth edition. The previous one was reviewed by us in 1910, but such are the advances in the study of diseases of the nervous system that text-books rather rapidly become

out of date. It was inevitable, for instance, that after a lapse of six years chapters on nervous syphilis and on the serology of nervous disease, on poliomyelitis and epidemic cerebro-spinal meningitis, would require to be largely rewritten, and Dr. Dana has, as a matter of fact, completely remodelled these and other important sections of his book. Among the latter may be specified the articles on the psychoneuroses; neurasthenia has been pushed rather into the background, in the sense that it has undergone a dismemberment; but the writer trusts that he has given a measure of justice to psycho-analysis, because of its place "in the interpretation and occasionally in the therapeutics of the minor psychoses." In its present attractive form Dr. Dana's text-book is assured of still wider recognition and appreciation. To those in search of a not too bulky but not too superficial treatise on neurology written mainly from the clinical viewpoint it can be confidently recommended.

*A Glossary of Botanic Terms, with their Derivation and Accent.* By BENJAMIN D. JACKSON. Third edition. London: Duckworth and Co. 1916. Pp. 427. Price 7s. 6d. net.—This glossary was first issued some 16 years ago by the author, who is the general secretary of the Linnean Society of London, with the object of supplying the student with concise definitions of the botanical terms he is likely to meet, and of helping the expert to recall an obscure term or word employed in a special sense, and the dual purpose has been well fulfilled. The total number of words in the glossary is now 21,000, and their definitions are precise and clear, while the selection of type facilitates easy reference. Obsolete terms are included in order that original papers or books of any period may be understood. The author acknowledges the assistance of a number of experts, including Sir Francis Darwin, in the preparation of the work for the press.

*Surgical Operations with Local Anæsthesia.* By ARTHUR E. HERTZLER, A.M., M.D., Surgeon to the Halstead Hospital. Second edition. New York: Surgery Publishing Company. 1916. Pp. 312. Price \$3.—We spoke favourably of this little book when it first appeared, and the additions which have been made to it will be found useful. The scope of the work has now been enlarged to include many surgical procedures which may certainly be described as major operations, but any surgeon who wishes to employ local anæsthesia should understand that practice is required to obtain the best results, and he will be wise at first to confine himself to the small operations. No doubt with practice some extensive operations can be performed satisfactorily under local anæsthesia, but it is doubtful if such an elaborate operation as the complete removal of the breast and of the contents of the axilla can be thoroughly carried out without a general anæsthetic. The book will serve its purpose as a trustworthy guide to the use of local anæsthetics.

*Fleas as a Menace to Man and Domestic Animals: their Life-history, Habits, and Control.* By JAMES WATERSTON, B.D., B.Sc. Economic Pamphlet, No. 3. Illustrat d. London: Trustees of the British Museum. 1916. Pp. 21. Price 1d.—The flea follows the house-fly and the louse in the pamphlets of the economic series issued by the Natural History Museum. Mr. Waterston, who is entomological assistant at the Imperial Bureau of Entomology, gives a short introduction stating the case against the flea as a carrier of disease, and then devotes ten pages to its structure and habits. The directions for the control of the pest are essentially practical and include the results of recent research.

## THE CONTROL OF VENEREAL DISEASES.

### Public Meeting in Belfast.

A very largely attended meeting, convened by Sir Crawford McCullagh, Lord Mayor of the city of Belfast, was held in the City Hall on Thursday, Jan. 18th. The Lord Mayor, who occupied the chair, said that the information placed before him by a large and influential deputation was a revelation and surprise in regard to the inroads venereal diseases had made into the life of the entire community. He advocated the formation of a strong council in Belfast to do all that could be accomplished to stop the terrible evil. Professor J. A. Lindsay, in proposing a motion to form a branch of the National Council for Combating Venereal

Diseases, gave a full account of the work of the Royal Commission and of its recommendations, and urged a forward movement. The Bishop of Down, Connor, and Dromore (Rev. Dr. D'Arcy), in seconding the motion, said he did so with a profound sense of duty, and pointed out that the present movement had nothing to do with the State regulation of vice, a line of action which he denounced as a mistake morally and an utter failure from the point of view of health, national and personal. The motion was supported by Sir John Byers, who dealt specially with the effects of venereal diseases on women and children, the economic loss to the nation caused thereby, and the relationship of the diseases to maternal and child welfare. He expressed himself as strongly in favour of notification. The Moderator of the General Assembly of the Presbyterian Church (Rev. Dr. West) moved, and Captain W. J. Wilson, R.A.M.C., specialist sanitary officer in the North of Ireland Command, and lecturer in hygiene and preventive medicine in Queen's University of Belfast, seconded a motion appointing a general and executive committee.

### Council and Other Schemes.

The City of London Corporation's scheme for the establishment of a treatment centre in Golden-lane has now received the approval of the Local Government Board, assuming that the Corporation are satisfied that the establishment of the centre away from a hospital will not deter patients from attending through fear of being recognised.—The county councils of East Suffolk and Norfolk and the county borough of Great Yarmouth are arranging with the city of Norwich for a combined treatment centre at the Norfolk and Norwich Hospital with six beds for patients of each sex and a laboratory with competent pathologist. The medical officer will visit outlying districts in a consultant capacity as occasion requires. The cost to the hospital for the first completed year of the scheme is estimated at £1600, of which the city of Norwich is to bear two-fifths.—Dr. F. Shuffebotham reported last week to the Shropshire county council that their public health committee was shortly to draw up a scheme including treatment centres at the North Staffordshire Infirmary (Stafford) and the Wolverhampton General Hospital.

### Enlightenment Campaign.

A little book entitled "Prostitution: The Moral Bearings of the Problem," just published by P. S. King and Son (239 pages, price 1s. net) for the Catholic Social Guild, contains an excellent chapter on Venereal Diseases by a former resident medical officer of the London Lock Hospital who signs himself "J. F." The whole subject-matter, while treated from the Roman Catholic standpoint, is, from a medical point of view, stated fairly and frankly. The Archbishop of Liverpool supplies a foreword containing wise thoughts on the value of modesty and the barrier set up against evil deeds by the exercise of control. The book cannot fail to have a useful influence in the sphere for which it is intended.

**LETTERKENNY MEDICAL OFFICERSHIP.**—At the Letterkenny board of guardians, on Jan. 19th, the party which had been in a minority in the previous week was now in the majority, and granted the money for medicines and appliances refused the previous week.

**EDINBURGH ROYAL INFIRMARY.**—At their recent meeting the general court of contributors to the Royal Infirmary remitted to a committee to consider the report of the managers and the accounts, and the report of the committee has now been prepared. It states that during the past year the managers had taken part with other institutions in the founding of a College of Nursing, the principal objects of which are to promote the better education and training of nurses, to form a register of fully qualified nurses, and to obtain a measure of State recognition for the profession. It is hoped to raise the status of trained nurses by the institution of this College and at the same time to secure adequate recognition of the important work they are performing for the welfare of the nation. A Scottish board has been created to supervise and control the work so far as Scotland is concerned, and the Royal Infirmary has direct representation on the board. The report of the committee of contributors referred to the proposal to give the miners a more distinct voice in the conduct of the institution. The miners had already increased their subscriptions and the managers found themselves in favour of the proposal to give them representation on the managing board.

# THE LANCET.

LONDON: SATURDAY, JANUARY 27, 1917.

## The Problems of Tetanus.

THE present war has set us many problems in the treatment of disease, and though much progress has been made in all sorts of directions, every step forward invariably reveals new paths inviting exploration. One of the most important diseases occurring in the armies on either side is traumatic tetanus. Here, indeed, much has been accomplished. It is uncontestedly proved that a prophylactic dose of tetanus antitoxin has a really wonderful effect in reducing the incidence of the disease; but from the very fact that through the use of the antitoxin an attack of tetanus is prevented arises a great difficulty in deciding in what proportion of cases the disease has been prevented by the antitoxin and in what proportion of cases the disease would not have occurred, even though no antitoxin had been given. Still the great fall in the number of cases in which tetanus occurs, even though other conditions have remained unchanged, tells us, without the possibility of error, that tetanus antitoxin has a very real action in the prevention of the disease. Almost as striking in its testimony to the value of tetanus antitoxin is the appearance of local tetanus and other modifications due to the effect of a prophylactic dose, insufficient wholly to prevent the disease but sufficient to modify it in one way or another. On this interesting aspect of the subject we print to-day a paper by Captain H. BURROWS, and we trust that similar observations are being made by the medical officers to whom the opportunity is given.

The main problems which have to be solved in regard to tetanus have been worked upon recently by Colonel Sir WILLIAM LEISHMAN and Major A. B. SMALLMAN, and the results that they have obtained are recorded in a paper appearing in the present number of THE LANCET. One question still open concerns even the prophylactic dose itself. It may be taken as conclusively proved that the prophylactic dose of tetanus antitoxin has a real and, indeed, great effect in preventing the occurrence of the disease, and it is equally clear that the earlier the prophylactic dose is administered the greater its preventive effect. But there was little exact knowledge as to the effects of delay, so an attempt was made by the authors to see if any precise information could be obtained hereupon, and details were sought as to the precise number of hours which had elapsed in a certain number of cases between the infliction of the wound and the injection of the tetanus antitoxin as a prophylactic. We are dealing only with cases in which the disease occurred in spite of the prophylactic injection, and the statistics

obtained by the authors show that the death-rate from the disease was very definitely less when the dose was given within 24 hours of the infliction of the wound, as compared with the death-rate in those cases in which the injection was given later. Also the statistics indicate clearly that the earlier the dose is given the longer the incubation of the disease. As to the therapeutic use of the antitoxin the difficulties of forming an exact opinion are admittedly great, but a careful examination of the facts seems to show that there is definite evidence that the mortality after doses of 20,000 units is less than when a smaller dose has been given. The route by which the antitoxin should be administered does not admit of exact dictation, mainly because the number of cases is but small, yet it may be said that the figures supplied by Sir WILLIAM LEISHMAN and Major SMALLMAN go to prove that the intramuscular and subcutaneous routes offer the best chance of a favourable result.

Another problem with which the authors have dealt is the association between the occurrence and fatality of traumatic tetanus and the region of the body which has been wounded. Roughly speaking, the figures in the paper would suggest that tetanus after a wound of the body is little more likely to prove fatal than when the wound is situated on a limb. There also appears to be proof that any operation after tetanus has declared itself has a tendency to increase the mortality; but be this as it may, it seems to be clear that it is wise to give a dose of antitoxin before operating, should an operation be needed. The number of cases investigated in the paper is only 160, but the purpose of the authors is served by their consideration, while the smallness of the number must be regarded as the result of the advance of our knowledge in the prevention of the disease, though it renders some arguments less forcible than they would have been had they been based on more material. In our opinion, the most important conclusions to be drawn from the work that Sir WILLIAM LEISHMAN and Major SMALLMAN have done, are these: That in the treatment of tetanus, when once it has declared itself, the intramuscular and subcutaneous routes should be selected in preference to any other; that the intrathecal route is by no means free from danger, and of doubtful efficacy; and that the intravenous route is no more efficacious, and is certainly more dangerous, than either the intramuscular or the subcutaneous methods. They are also of opinion that the dose of antitoxin should be large; if the intramuscular and subcutaneous routes be chosen the dose should be not less than 10,000 units per day for the first few days. It appears advisable that the administration of the antitoxin should not be abandoned too early, for recurrences may occur. It is obvious that it has been sometimes difficult for the authors to draw clear conclusions from the material obtainable. The problems are extremely complex; so many factors enter into every one of them that the results run no small risk of being vitiated by disturbing elements. But we have

no doubt that a valuable service to the study of tetanus has been rendered by Sir WILLIAM LEISHMAN and Major SMALLMAN in the investigation which we publish to-day.

### The Practice of Massage.

THE function of an unused muscle is soon diminished or lost, and when the normal stimulus to contraction fails in part or wholly to reach it through its motor nerve the application of various forms of mechanical and electrical stimulation may have a useful place. The familiar physiological fact which lies at the root of all such treatment is that of the three essential parts of the motor apparatus it is the nerve cell which most readily becomes fatigued, next the muscle fibre, and only at long last the conducting nerve fibre. Where the activity of the nerve cells has been reduced by disease, disuse, or shock, much can be done by massage and appropriate electrical methods to keep the other elements of the motor apparatus in good condition until normal nervous energy is again forthcoming. The normal route is the best one; no other muscle stimulus can entirely take its place, and massage must always be looked upon as a second best. The war, indeed, with its myriads of stiffened and disused muscles has not only brought massage very much to the fore, but has given an indication of the limitations of massage and of the superiority in many cases of active and semi-active movements of the crippled limbs. All has not been done when the patient has been handed over for so long every day to a professional rubber. The indications for massage must be a matter of exact study, and skilled massage may be largely wasted when the surgeon has not been able to prescribe it correctly. There is room—urgent need, indeed—for the accurate scientific study of the indications for massage in order that the supply shall be allotted to the cases which most require it and will gain most benefit therefrom.

The supply of trained masseurs—a term which may conveniently include both genders—has been vastly increased during the war, and the demand is still unsatisfied, although, as we have hinted above, no great certainty exists that they are all being employed on essentially useful work, and that the supply is really insufficient to meet the exact indications for their services. The examination of the trained has in the past been in the hands of the Society of Trained Masseuses, founded in 1894 and incorporated six years later, with its headquarters at 157, Great Portland-street, London, W. The present position and attitude of this society, which has recently granted certificates to men as well as to women, may be seen from a letter circulated last autumn to all hospitals and schools where students are prepared for the society's examinations, the substance of which is as follows:—

The Incorporated Society has endeavoured to fulfil all the requirements of the medical profession, and from its foundation in 1894 has had the support of medical men and women and their active assistance in exami-

nation. The recently appointed Advisory Board of the Society is representative of professional interests. The examination in medical electricity inaugurated by the society since the outbreak of war is entirely conducted by members of the medical profession, who also take part in the other examinations, including those for massage, Swedish remedial exercises, and teachers' certificate. The written part of all examinations is held at local centres, and for years past a practical examination has been held in Dublin and more recently, in response to a demand, in Liverpool and Manchester. Certificate-holders now number 3990 (men and women).

Whilst the pioneer work of the schools of massage included in the London Society has been fully recognised, the feeling has grown that on the one hand students as well as teachers of massage were at some disadvantage in the provinces as compared with the trainees in the metropolis, and on the other hand that the public and the medical profession, as well as the practice of massage itself, would gain by the establishment of a widely representative society directly under medical control, with a board of management elected annually to represent the medical profession and the various charitable institutions. The proposal materialised during the second year of the war in the formation of an Institute of Massage and Remedial Gymnastics. A meeting was held under the presidency of Sir WILLIAM COBBETT, chairman of the board of management of the Manchester Royal Infirmary, a scheme was drawn up embodying the views set forth above, and an organising committee was appointed, with the result that the Institute was formed and its articles of association licensed under the Board of Trade. The first general meeting was held at the Manchester University on Nov. 10th last, when Sir WILLIAM MILLIGAN outlined the scheme, which includes a provision that one-half of the ordinary members of the council (of whom there may be 20) shall be nominated by not more than ten charitable medical institutions of a public character. Honorary Fellows will be elected by the council from members of the medical profession, and a board of examiners will be appointed, to consist of members of the medical profession and persons possessing the necessary technical knowledge. The Institute of Massage is thus a purely examining and certifying body. No fees can be accepted by acting members of the council, and its constitution forbids those concerned in massage for a living from exercising active control in its affairs. We understand that amongst the Fellows of the Institute are the names of many prominent medical men in London, Manchester, Edinburgh, Bristol, and other large centres. The Institute of Massage and Remedial Gymnastics is therefore founded upon lines with which the medical profession can cordially agree, and the energy of its founders should carry it far. It is less evident that it can afford to dispense with the accumulated experience and the training facilities of the Incorporated Society of Trained Masseuses. It would probably be to the advantage of the practice of massage if the useful work which is being done by each separately could be done in common. We trust that conference between the two bodies will result in a working agreement.

## Annotations.

"Ne quid nimis."

### TOXIC JAUNDICE.

AN important discussion on toxic jaundice took place on Tuesday at the Royal Society of Medicine in the combined Sections of Medicine, Pathology and Epidemiology. Surgeon-General Rolleston occupied the chair and the discussion was opened by Dr. T. M. Legge, medical inspector of factories, who communicated an analysis of the reports of 105 certifying surgeons on jaundice due to absorption into the body of tri-nitro-toluene. The discussion which followed was an exhaustive one, bearing on pathology, treatment, and prophylaxis. We are unable to do more this week than publish Dr. Matthew J. Stewart's careful study of the changes in the blood and liver cells; the former during life, the latter from 12 cases of accidental death in munition workers. The blood changes point to a progressive failure of the leucoblastic function of the bone marrow as a frequent, but not quite constant, manifestation of tri-nitro-toluene poisoning. The degenerative changes in the liver, once set going, were found to be progressive, even after removal of the patient from contact with the poison. Dr. Stewart's work illuminates one side of a new and very important question to which we shall have occasion to return.

### THE EXPLOSION IN EAST LONDON.

THE enormous potentialities of the modern explosive were illustrated painfully in the recent disaster in East London, but we may well express wonder and admiration that such serious occurrences have been so comparatively rare since the gigantic work of making munitions all over the country was begun. The substantial immunity from disaster hitherto enjoyed has been due, of course, to the extreme precautions that have been insisted upon by the munition authorities and their loyal observance by the workers. It is valueless to speculate as to what happened in the present instance without stating the grounds for the different theories, and this would be a wrong course. We know that an ordinary fire had started in the factory which proved to be too rapid in its march upon the dynamic powder, although brave and splendid efforts were made to quench this fire, during which the operatives were warned to leave the building. This, no doubt, saved a number of lives, for although the loss of life outside the factory was considerable—and the list will yet be added to from a crowd of seriously hurt—the totals of killed and injured are far lower than the circumstances could have warranted. The chief chemist, Mr. Andrea John Angel, M.A., B.Sc., who perished in his endeavour to cut off the fire from the explosive material, sacrificed his life to save others, and his last deed was truly a noble one. He knew more than anybody what the fearful possibilities were, and he worked in the last moments of his life in the hope of fending them off. The explosion, though limited in its dire results by much prompt and brave action, has caused widespread havoc and misery, and the whole nation is expressing its deep and practical sympathy with the

bereaved and the suffering. A tribute is due to the promptitude with which medical aid was forthcoming; no effort was spared in the ghastly work of rescue, in removing the injured to hospital for treatment, and in placing those so suddenly and cruelly deprived of their homes under shelter where food and what other comforts could be offered them were provided.

### FLAVINE.

THE search for an efficient germicide within the body has gone on for half a century with undiminished enthusiasm, although the number has latterly increased of cautious people who contend that the search must be a hopeless one, because any agent that destroyed the living bacterial protoplasm would also be potent to harm the living tissue cells. The history of the treatment of phthisis has been one long attempt to find some substance more harmful to the tubercle bacillus than to the lung tissue; and the complete failure to find such a substance in the prolonged opportunities of a chronic disease has made success seem less likely in the case of short-term infections. Ehrlich's discovery of organic arsenical compounds such as "606" and "914," which fulfilled the conditions as regards spirochaetes, raised drooping hopes, and Sir Almroth Wright's application of Morgenroth's optochin to the chemo-therapy of pneumonia was an apparently successful piece of germicidal work on bacteria in the living body. Optochin proved not merely germicidal in extreme dilutions quite innocuous to the tissue cells, but was equally effective in the presence of the albuminous fluids of the blood. Since then claims have steadily grown for the germicidal properties of various anilin derivatives, methylene-blue, scarlet red, and brilliant green. Emery called attention in THE LANCET of April 15th, 1916, p. 817, to the high germicidal value of malachite green, finding it, in a piece of work carried out for the Medical Research Committee on a standard method of testing antiseptics for wounds, the most powerful antiseptic he investigated. Working with the *Streptococcus faecalis*, a crescendo series of values was given by biniodide, phenol, perchloride, lysol, malachite green. A further improvement on the last named has now been made by Captain C. H. Browning, R.A.M.C., and his collaborators in the rediscovery of flavine, an acridine derivative of complicated formula originally prepared by Benda at the request of Ehrlich, and found to have a marked therapeutic effect in trypanosome infections. The work was carried out with the aid of grants from the Royal Society's Scientific Grants Committee and the Medical Research Committee in the Bland-Sutton Institute of Pathology at the Middlesex Hospital, and published in the *British Medical Journal* of last week, when the chain of evidence for its claim was established by experimental and clinical data. The potency of flavine is not merely unimpaired by the blood proteins: it is enhanced by them, and its lethal concentration for *Staphylococcus aureus* in serum is one-tenth that required in peptone water. The factor on which the authors lay most stress is what they call the therapeutic coefficient, being the quotient of the concentration of the antiseptic which reduces phagocytosis to one-half and the concentration just sufficient to kill *staphylococcus* in serum. This coefficient for flavine reaches the astonishing value of 400, as compared with 6 for malachite green and  $\frac{1}{4}$  for

eusol. Flavine is practically a selective bactericide. Fourteen months' testing in the casualty department of the Middlesex Hospital has substantiated the results obtained *in vitro*, and a paper by Mr. D. Ligat, acting assistant surgeon to the hospital, relates his favourable experience with the treatment of some 75 war wounds with brilliant green and flavine, of which the latter gave the better results. The preparation of flavine has been worked out under the supervision of Dr. Barger in the laboratory of the Department of Biochemistry (Medical Research Committee). A supply of it will later be available on application to Captain C. H. Browning at the Bland-Sutton Institute, and the result of independent investigations will be awaited with interest.

#### DIABETES INSIPIDUS AND LESIONS OF THE POSTERIOR LOBE OF THE PITUITARY BODY.

VARIOUS changes have been described from time to time as having been noted in the pituitary body and the neighbouring parts of the base of the brain in cases of diabetes insipidus. It is not yet, however, quite certain what are the structures involvement of which is essential for the production of that condition. Camus and Roussey have proved experimentally that polyuria may result, although the pituitary gland proper is not implicated. It would appear that the infundibulum is of some importance in this connexion, as in one observation removal of the pituitary gland with preservation of the infundibulum was not followed by polyuria. Ependymitis and other lesions of the floor of the fourth ventricle, including Claude Bernard's famous experimental puncture, have resulted in the appearance of either simple polyuria or diabetes insipidus. Further, a number of cases have been reported of diabetes insipidus occurring in association with basal lesions of a meningitic nature, either syphilitic or tuberculous or otherwise. In the December number of the *American Journal of the Medical Sciences* Dr. F. Parkes Weber and Dr. Hans Schmidt, of the German Hospital in London, have recorded a case of this description, where a tuberculous patient suddenly developed diabetes insipidus about two years before his death, which was due to pulmonary and laryngeal tuberculosis. The urine was of about the same specific gravity as ordinary tap-water, pale, clear, and free from sugar or albumin, and averaged about 10 litres in the 24 hours. The Wassermann test in the blood serum was negative. There were no fundus changes, no hemianopia, and no radiographic evidence of alteration of the sella turcica. Macroscopically the hypophysis did not appear enlarged, but it was obviously abnormal in its posterior lobe, a change which was readily confirmed microscopically. In proportion to the anterior lobe the posterior was much enlarged, the latter completely enclosing the former and being of a yellowish-brown colour. In the posterior lobe were found large clusters of what looked like compound granular cells; they were large cells with small nuclei staining deeply with haematoxylin. Their cytoplasm had a granular appearance, containing in reality innumerable minute droplets of a lipoid substance; hence, no doubt, the peculiar colour of the lobe, resembling the colour of the suprarenal cortex. The authors have not been able to find any record of a similar change in other reported cases, nor do they theorise on the possible connexion between the clinical and the pathological conditions. The case, nevertheless,

is of some documentary value, especially as the nervous system, apart from the pituitary gland, was found on examination to be normal, while the other ductless glands were also normal, both macroscopically and microscopically.

#### CHILD WELFARE WORK.

AT the Royal Institute of Public Health last week Dr. Janet Lane-Claypon read a paper on the principles of organisation and administration in relation to child welfare work, which laid full stress on matters the importance of which the public is beginning to appreciate. The period between infancy and the commencement of school life constituted, she said, an important gap in hygienic control. Children of from 3 to 5 years developed ailments which were generally first discovered and dealt with when they went to school. By this time the simple measures sufficient to relieve might no longer be of avail. Dr. Lane-Claypon looks forward to the State aid and organisation of many branches of social work now carried on by voluntary agencies. Lecturing at the house of the Royal Society of Medicine, 1, Wimpole-street, on Monday last, by arrangement with the National Association for the Prevention of Infant Mortality, Dr. E. Pritchard welcomed the legislation in regard to the proper care of the new-born child foreshadowed by Lord Rhondda as President of the Local Government Board. A medium of useful publicity in the whole field of medical and social work for mothers and babies is afforded by a new monthly journal entitled *Maternity and Child Welfare* (John Bale, Sons, and Danielsson. Price 6s. per annum, post free), of which the first number has just reached us. This number contains two valuable articles by the medical officers of health of Birmingham and St. Pancras respectively, Dr. J. Robertson on Welfare Work and Dr. T. S. Higgins on the Prevention of Measles Mortality. An editorial note briefly sketches the history of welfare work, commencing with the "Consultations de Nourrissons" at the Nancy Maternity Hospital and Professor Budin's work at Paris hospitals; in this country, with the infant milk dépôt at St. Helens established by Dr. J. J. Buchan, medical officer of health, in 1899, and the foundation of the first school for mothers in the borough of St. Pancras eight years later. The appearance of this new journal is fully justified, even at the present time, and we forecast a sphere of great practical usefulness for it.

#### EPIDURAL INTRASPINAL ABSCESS OF METASTATIC ORIGIN.

IN the *Boston Medical and Surgical Journal* of Dec. 14th last Dr. W. J. Mixter has reported a case of paraplegia due to a very rare cause—epidural abscess—which is overlooked in the text-books. Its recognition is important, as early operation offers a favourable prognosis. A youth, aged 17 years, was seen in consultation. Sixteen days previously he began to suffer from pain, increased on respiration, in the left shoulder and about the left side of the chest at the level of the fifth rib. He also complained of sore-throat. He remained at home from school for a few days and improved enough to return, but was still uncomfortable and evidently not in good health. Five days before he was seen acute retention of urine occurred. He was catheterised and examination of the urine

was negative. The next day he developed stiffness and weakness of the legs, headache, and stiff neck. The retention persisted and was rapidly followed by spastic paraplegia with temperature of 101° F., and he was taken to the hospital. Lumbar puncture yielded clear fluid, not under excessive pressure, the temperature rose steadily and paralysis became complete in the legs. On examination the temperature was 105°, pulse 118, respiration 24, blood pressure 120, and the leucocytes numbered 30,000. There was marked furunculosis of face. The throat was somewhat reddened. He was slightly confused mentally. The pupils were normal. There was no choked disc. The head was held turned somewhat to the left and the neck was stiff. There was definite ataxia of hands, but no motor or sensory paralysis of arms or hands. The arm reflexes were not increased. A definite zone of hyperesthesia was present from 7-9 D, and there was complete anaesthesia below that level. The legs were paralysed and there was priapism. Skin reflexes: abdominal not obtained, cremasteric equal and normal on two sides, normal plantar on left, Babinski on right. Tendon reflexes: knee and Achilles jerks not obtained. Kernig's sign absent. Lumbar puncture yielded clear fluid with very faint yellow tint, not under pressure, which showed a definite coagulum on standing. Laminectomy was performed from the third to the sixth dorsal vertebrae inclusive. Beneath the epidural fat and outside the dura was found a cylindrical abscess cavity running from the third cervical to the first lumbar vertebra and containing creamy, greenish-yellow pus under considerable tension. No evident focus of infection could be made out. The abscess cavity was drained with rubber and the wound closed rapidly. The patient died a few hours later. No necropsy was allowed. The pus showed a pure culture of *staphylococcus aureus*. Evidently there was transverse myelitis due to an acute process; an abscess was thought the most probable. Dr. Mixter thought the abscess to be metastatic from the furunculosis or from tonsillar infection. The possibility of extension from osteomyelitis of a vertebra must be considered, but the condition found on operation seemed to negative this. While extradural abscess formation of this type is rare, its importance is considerable in that operation undertaken early should relieve the paralysis and bring about a cure. The prognosis should be considerably better than when the abscess is secondary to infection of the spine.

THE LANCET, VOL. II., 1916 :  
THE INDEX.

OWING to the continued shortage in the paper-supply the Index and Title-page to the volume of THE LANCET which was completed with the issue of Dec. 30th, 1916, have been printed separately, and copies have been supplied gratis to those subscribers who have, up to Jan. 25th, intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted, on application to the Manager, THE LANCET Office, 423, Strand, London, W.C. Such applications should be sent in at once.

OUR contemporary the *Scotsman* celebrates the 100th anniversary of its birthday as we go to press. We congratulate the journal on its well-earned success, especially as it provides its readers with a steady supply of well-considered medical information of exactly the kind that benefits the public.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Rerudescence of Rabies.*

FOR some time past there has been throughout the whole of France an increase in the number of cases of rabies. Rabies has for a long time been epizootic in this country, but it is certain that the situation will be kept well in hand if the regulations are seriously applied. In the Department of Seine cases of hydrophobia in man have been entirely suppressed for some years, thanks to the systematic capture of stray dogs. At the outset of the war the abandonment of a large number of dogs in consequence of the general mobilisation and of the exodus from Paris gave rise to some anxiety. In September, 1914, the Prefect of Police instructed local mayors and commissioners of police to take all necessary precautions. The number of captures of ownerless dogs rose to 4860 and observation showed that they had been for the most part abandoned by their owners, who removed the collars in order to avoid responsibility. The precautionary measures bore fruit, for in Paris from July, 1915, to March, 1916, there was no case of rabies and treatment at the Pasteur Institute was numerically much reduced, but from May, 1916, on the cases began to increase. Happily for Paris the city and even the department have not been affected by this recrudescence, but it must not be forgotten that more than a careful search for stray dogs is required. The sympathetic public must be put on guard against the danger of giving shelter to stray dogs found wandering in public places, for it cannot be known whether they have not been contaminated by the accidental introduction into Paris of dogs bitten and infected outside.

*Professional Re-education of Soldiers.*

A conference on the professional re-education of war cripples, arranged by the Belgian Government, with the cooperation of the French Government authorities, will be opened on March 6th at the Ministry of Labour and Social Welfare in Paris. The conference will have before it very important questions to examine, such as the re-establishment of the functions of limbs injured by gunshot wounds, the replacement of the war cripple in his proper surroundings, his re-adaptation to a new profession, the attempt to raise him to a superior level and to place him under the most advantageous conditions for himself and society at large; in brief, to assure to the war cripple a permanent living. The whole constitutes a task of which the magnitude and necessity are obvious, as well as the great difficulties attached to its execution. To surmount these difficulties the common experience acquired during the first two years of war in the allied countries is to be placed under contribution.

*Poisoning by Motor-gas in Ambulances.*

M. Tanon, at a medical reunion of the 5th Army, drew attention to the inconveniences attendant on the heating of ambulances by the exhaust-pipe of the motor. When the latter functions badly and the joints of the tube are not close a discharge of gas may occur in the interior of the carriage, and result in consequences which in certain cases have been fatal. Similar facts were observed before the war with certain touring cars. The mechanism of the poisoning is not quite simple, for the quantity of carbon monoxide mixed with the gas is minimal, although the lesions observed at autopsy point distinctly to carbon monoxide poisoning. The red blood cells were not destroyed nor was the haemoglobin reduced in the researches made by the pharmacist, Major Ebren. Blood impregnated with hydrocarbons was found to be still capable of absorbing oxygen. The toxic action is more complex, and exerted apparently both on the respiratory apparatus and on the medulla. The early symptoms seemed to be due to a toxic action on the medulla. In view of these observations officers in charge of ambulances should observe great care in supervising carriages warmed in this way, and should direct the chauffeurs to assure themselves of the condition of the patients every time the motor functions badly.

*Increase of Consultation Fees.*

The Association of Medical Men in the Department of the Seine decided, at its last meeting, presided over by Dr. Leredde, to increase the standard of medical fees by 25 per

cent. for all persons whose financial position has not been changed for the worse by the war. The increased charge is naturally aimed at the numerous patients whose position has been actually improved by war conditions. A merchant in any kind of wares may, by common consent, raise his prices in proportion to new charges which fall upon him, and the medical man unquestionably possesses the same right when he is mulcted by increased taxation. The doctors only desire to make their fees proportional to the situation of the people who claim their services. In ordinary times, be it remembered, they have always lost some 15 per cent. of fees in bad debts, which were for the most part unredeemable.

#### *Reinforced Quinine Treatment of Malaria.*

M. Carnot has dealt with this subject at a recent meeting of the Medical Society of the Hospitals, claiming that treatment is insufficient in many cases of recent malaria when quinine is administered by the mouth even in a dose of 1·5 gm. He insists on the great advantage of the intravenous route of administration, one or two ampoules, each containing 0·4 gm. of quinine and 0·2 gm. of urethane in 1 c.c. of water diluted to 20 c.c. with normal saline being injected. This combined method reinforces the action of quinine in pernicious forms of the disease, especially when these are afebrile.

Jan. 22nd.

## THE SERVICES.

### ROYAL NAVAL MEDICAL SERVICE.

To be temporary Surgeons: L. Baxter, N. S. Hewitt, W. O. Lodge, W. J. C. Watt, R. W. Pritchard, and J. P. Ross.

### ROYAL ARMY MEDICAL CORPS.

To be temporary Lieutenant-Colonels: Sir Arthur Chance, A. B. Mitchell, and H. V. Rigby (Captain, R.A.M.C., T.F.).

Temp. Capt. C. D. Pye-Smith to be temporary Lieutenant-Colonel whilst in command of a Field Ambulance.

The undermentioned relinquish the acting rank of Lieutenant-Colonel on requesting: Major H. W. Long, Temp. Capt. J. La F. Lauder, D.S.O., and Temp. Major C. E. L. Gertwood.

Majors to be acting Lieutenant-Colonels whilst in command of a General Hospital: M. C. Wetherell and Arthur W. Gater.

To be Acting Lieutenant-Colonels whilst in command of a Casualty Clearing Station: Brevet Lieut.-Col. FitzG. G. Fitzgerald and Major J. H. R. Winder.

Capt. A. M. Pollard to be acting Lieutenant-Colonel whilst in command of a Field Ambulance.

Capt. E. M. Midleton to be acting Major whilst in command of a Field Ambulance.

Lieutenants to be temporary Captains: C. E. A. Huddart, T. H. Oliver, J. Ross, J. K. Cheesman, D. K. MacDougall, H. F. Bruce-Smith, G. S. Terry, J. P. O'Connor.

To be Lieutenants: Captain J. A. W. Ebden (R.A.M.C., Spec. Res.) with temporary rank of Captain, T. C. Bowie, G. C. Robinson, D. H. Coats, C. B. C. Anderson (R.A.M.C., Spec. Res.), P. E. D. Pank, G. Moulton, and R. H. C. Prym (from R.A.M.C., Spec. Res.).

O. P. N. Pearn to be temporary Captain whilst employed at the Lord Derby War Hospital.

Temporary Captains relinquishing their commissions: O. P. N. Pearn, J. Hanson, A. H. R. Duncan, F. J. Dixon, F. McKee, R. G. Brown, R. D. Forbes, J. E. M. Brown, A. W. Anderson, H. H. Prentiss, N. I. Sinclair, J. A. K. Bravton, S. G. Billington, G. W. Charley, E. C. A. Smith, P. J. S. O'Grady, F. G. O'Donnell, N. R. Rawson, A. V. J. Harrison, F. S. Rowland, D. H. Griffiths, G. E. Genge-Andrews, E. B. H. Bon, J. S. Hall, F. A. Murray, H. L. Aphorn, W. R. S. Watkins, T. J. Burton, P. Butler, J. E. Cook, J. Allan, R. B. Taylor, M. Haynes, J. S. Martin, J. Allison, H. S. Berry, H. Catling, G. Coats, R. S. Miller, F. Ayre (on account of ill-health).

Surgeon-Capt. A. J. Clarke (Overseas Contingent, B.W.I. Regiment) relinquishes his commission.

Temp. Hon. Cap. A. E. Ward, having resigned his appointment at the Springburn and Woodside Central Red Cross Hospital, relinquishes his commission.

Temporary Lieutenants relinquishing their Commissions: G. W. Racey, S. E. T. Suann, J. A. Davidson, A. Chancé, H. S. Sims, R. M. Moore, R. Paterson, H. Denison (on account of ill-health).

### SPECIAL RESERVE OF OFFICERS.

To be Lieutenants: G. G. Jack, D. Mitchell, H. C. Roberts, C. Tighe, B. Mountain (from University of London Contingent, O.T.C.), J. A. Charles, J. B. Leish (from Manchester University Contingent, O.T.C.), W. B. Lawson.

Captains to be acting Lieutenant-Colonels whilst in command of a field ambulance: (Acting Major) R. Magill, W. H. L. McCarthy, W. R. Gardner.

### TERRITORIAL FORCE.

Capt. W. A. Slater, from 1st Northern General Hospital, to be Captain.

Capt. K. B. Clarke relinquishes his commission on account of ill-health, and is granted the honorary rank of Captain.

Capt. C. A. Spunner is seconded for duty with a hospital abroad, and Capt. J. N. Robbins is seconded while holding the appointment of Deputy Assistant Director of Medical Services.

John Steedman to be Lieutenant.

Lieuts. K. F. M. Davison, G. L. Findlay, and G. D. Newton to be Captains.

Major J. S. Mather relinquishes his commission on account of ill-health and is granted the honorary rank of Major.

Attached to Units other than Medical Units.—Major R. J. R. C. Simons relinquishes his commission on account of ill-health, and is granted permission to retain his rank and wear the prescribed uniform.

### TERRITORIAL FORCE RESERVE.

Surgeon-Major G. O. Parsons, from Glamorgan R.G.A., to be Surgeon-Major.

### DEATHS IN THE SERVICES.

Lieutenant-Colonel C. M. Thompson, I.M.S., on Dec. 24th, 1916. He entered the service in 1881 and served in the Tirah Expedition in command of the 44th N. F. Hospital, 3rd Brigade, was present at the actions of Chargu Kotal, Dargai, passage of Datoof Defile, Samaghia Pass and took part in the operations in the Wazir Valley and in the Bara in 1897 (medal and two clasps). Subsequently he was appointed Civil Surgeon at Outramkund and later Staff Surgeon at Secunderabad, being appointed senior medical officer of the General Hospital, Madras, in 1919. He was Principal of the Madras Medical College until 1911. Since the commencement of the war and up to a year ago he was employed temporarily at the Home for Indian Soldiers, Barton-on-Sea.

## VITAL STATISTICS OF ENGLAND AND WALES FOR 1916.

THE following statement shows the birth- and death-rates and the rates of infant mortality in England and Wales, and in certain parts of the country during the year 1916, the figures being provisional:—

	Death-rate per 1000 living.*	Deaths under one year per 1000 births.
England and Wales... ... ... ...	14·0	91
96 great towns, including London (populations exceeding 50,000 at the Census of 1911) ... ... ...	14·4	98
148 smaller towns (populations from 20,000 to 50,000 at the Census of 1911) ... ... ...	13·0	90
London ... ... ...	14·3	87

\* The death-rate for England and Wales is based upon deaths in the whole population and an estimated total population of 36,250,000. The birth-rate is similarly calculated as 21·6 per 1000. The death-rates for the towns are based upon civil deaths and estimated civil population. The birth-rates cannot be stated. In all cases the population used relates to the year 1915.

## URBAN VITAL STATISTICS.

(Week ended Jan. 20th, 1917.)

**English and Welsh Towns.**—In the 96 English and Welsh towns, with an aggregate population estimated at nearly 18,000,000 persons, the annual rate of mortality during the week was equal to 16·2, against rates steadily declining from 23·7 to 16·8 per 1000 in the four preceding weeks. In London, with a population of over 4,000,000, the death-rate was 6·5, or 1·1 per 1000 below that in the previous week; among the remaining towns it ranged from 6·8 in Dewsbury, 9·7 in Wakefield, and 10·0 in Coventry, to 23·5 in Exeter, 26·6 in Oxford, and 27·9 in Bath. The principal epidemic diseases caused 238 deaths, which corresponded to an annual rate of 0·7 per 1000, and included 82 from measles, 59 from diphtheria, 56 from infantile diarrhoea, 24 from whooping-cough, 9 from scarlet fever, and 8 from enteric fever. The deaths from measles were 1 in excess of the average in the three preceding weeks, and caused a death-rate of 1·3 in Coventry, 1·5 in Birkenhead, and 3·7 in Wimbledon. The 812 cases of scarlet fever under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospitals showed a further decline, while the 1396 cases of diphtheria were 1 in excess of the number at the end of the preceding week. Of the 5375 deaths from all causes in the 96 towns, 211 resulted from violence. The causes of 60 of the total deaths were uncertified, of which 20 were registered in Birmingham, 5 in Manchester, and 4 each in London and Liverpool.

**Scotch Towns.**—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death-rate was equal to 17·6, against rates declining from 19·6 to 18·1 per 1000 in the four preceding weeks. The 356 deaths registered in Glasgow were equal to an annual rate of 16·6, against 16·5 per 1000 in London, and included 7 from measles, 5 from infantile diarrhoea, 4 from whooping-cough, and 1 each from enteric fever and diphtheria. In Edinburgh the 108 deaths corresponded to an annual rate of 17·0 per 1000, and included 1 fatal case of whooping-cough and 1 of diphtheria.

**Irish Towns.**—The 187 deaths registered in Dublin were equal to an annual rate of 24·4 per 1000, and included 3 from measles and 1 each from scarlet fever, whooping cough, diphtheria, and infantile diarrhoea. In Belfast the 147 deaths corresponded to an annual rate of 19·5 per 1000, and included 7 from infantile diarrhoea, 5 from measles, 3 from whooping-cough, 2 from diphtheria, and 1 from enteric fever.

"Audi alteram partem."

### THE PROPHYLAXIS OF VENEREAL DISEASES.

*To the Editor of THE LANCET.*

SIR.—The critical and helpful articles that were published in THE LANCET and the *British Medical Journal* on Jan. 13th have led me to ask for space in your columns for a few remarks on this subject which, essentially medical though it is, is of high concern to the whole community. Since the appearance of my letter in the *Times* of Jan. 6th I have had numerous communications from various quarters indicating such concern, as well as a wide-spread conviction that medical men should make known to their patients generally those means of prophylaxis against venereal infections with which pathological science has in recent years supplied them. Up to now, however, although the public have been very generally and rightly instructed of late with respect to the multiform and dangerous results of syphilis and gonorrhœa, and also to the necessity of prompt treatment after these diseases have been contracted, a general silence has prevailed on the matter of prevention, not only on the part of the many lay members of the community who have earnestly and successfully promoted the important measures which have now found accomplishment, but also of the medical profession at large, inclusive of that special section of it which is devoted to the guardianship of the public health. The reason of this public attitude on the part of the medical profession generally—I am not forgetting the many individual medical men who are in no wise reluctant to aid in checking the spread of these infections by imparting their knowledge as freely as possible—is not far to seek. Medical men are hampered in this action by the “mediaeval doctrine” which, though it may not be expressed in words, is still operative in leading the public to regard sexual diseases from a different standpoint from that which they maintain towards all others. While the more prominent and powerful lay promoters of the recent great advance made in informing the public of the dangers of venereal diseases decline to take notice of the paramount importance of preventing infection at its source, it is perhaps scarcely to be wondered at that the medical profession as a body has not entered into an undertaking which, without some encouragement, would at least be difficult and liable to miscarry a rapid success. It is undeniably true that neither moral nor religious instructions will succeed in the future any more than they have succeeded in long past centuries in checking to any considerable extent the gratification of sexual instinct in both sexes by “irregular intercourse.”

The danger of venereal infection has been long held out as a physical deterrent, but with little or no effect, and no adequate result in this direction can be expected from the more detailed accounts of these dangers that have lately been given to the public. However great the dangers, the fact remains that only a comparatively small proportion of either sex, with the exclusion of regular prostitutes, contract syphilis or, indeed, gonorrhœa; and thus the risk is constantly taken even by those who are well aware of what consequences are entailed by failure to escape infection.

In a private letter to me Sir James Crichton-Browne, who has granted my request to be permitted to use it as I like, says:—

If syphilis were an inevitable ordained consequence of irregular sexual intercourse something may be said for leaving it alone; but as it is only a very occasional consequent it can be but feebly deterrent, if deterrent at all, and ought to be unhesitatingly prevented in every possible way. The prevention of syphilis and the prevention of immorality should be kept wholly distinct from each other. The Government have interdicted the sale of whisky less than three years old, the object being that in maturing it may be freed from the ingredients that produce injurious effects on the consumer. But, according to the opponents of the prevention of syphilis, that must be all wrong. The rarer the whisky—the more fused oil in it, the better; so that men may be prevented from drinking by the dread of delirium tremens. I remember Lord Houghton's telling me that at the time of the discussion on the “Contagious Diseases

Act” he had some conversation with Mrs. Butler. At last he said to her, “It seems to me that you regard the syphilitic virus as a beneficent moral agent. Now, tell me, if you had that virus locked up in a box and you had the key, would you keep it locked up or would you let it loose upon humanity?” Mrs. Butler vouchsafed no answer.

I wholly agree with the criticism in the *British Medical Journal* that effective measures of prevention must have regard to both sexes, “it being at least as likely that one infected woman will infect many more, as that one infected man will infect many women.” This fact is ignored in much that has lately been spoken and written on this subject. The dissemination of the disease by the male has especially attracted attention now owing to the assumption, based, I suppose, on some ascertained facts, that large numbers of infected soldiers will return to this country during and after the war. It is on this assumption at least that a special plea of urgency for prompt and effectual treatment of the disease was put forward when financial aid from the State, for this purpose, was recently sought and successfully obtained. I do not hesitate in expressing my opinion that doctors not only are justified in spreading the knowledge we now possess of effectual prophylaxis in respect to venereal disease, but also are bound in duty to do so in view of their knowledge of the results of disease, and of their functions as promoters of the public health.

Suggestions have been made to me for the forming of an association of medical men and others with human interests for promoting the knowledge of effectual prophylaxis against venereal diseases; but it seems clear that an initiative in this direction would be taken with far better prospects of quick success at the present juncture, if not by the Local Government Board itself, by the existing Society of Medical Officers of Health. The question is, and should be, regarded as exclusively medical. The time has come for plain speaking and prompt action on the part of the medical profession. In the words of THE LANCET article, “preventive treatment is a logical step forward, and ought to be taken at once.”—I am, Sir, your obedient servant,

Jan. 23rd, 1917.

H. BAYAN DONKIN.

### THE PHENOMENA OF ANAPHYLAXIS.

*To the Editor of THE LANCET.*

SIR.—I have read with the greatest interest and with much benefit Captain S. Wyard's excellent article on the phenomena of anaphylaxis in your issue of Jan. 20th, and, while I do not remember reading a clearer exposition of the subject, yet there are points not clear to me. It is the clinical point of view in which I am most interested.

In dealing with the sensitisation of man, Captain Wyard speaks of “considerable,” “small,” and “massive” doses of serum. He specifies what he means by a “small” dose, but he does not do so of the terms “considerable” and “massive.” He says: “Persons receiving massive injections are not, or, at all events, not always, hypersensitive after six weeks.” Again: “A massive first dose in many cases requires longer to produce hypersusceptibility than a smaller.” Again: “The anaphylactic state after two or three small doses may still be absent 28 days after the last;” and again: “Until proof to the contrary is forthcoming, it must be assumed that anyone who has received one or more injections more than 14 days previously is in this state”—(susceptibility to anaphylaxis).

I am unable to follow him as precisely as I could wish. And I would be much obliged were he to help me, for I am not writing in a captious spirit. I feel sure he will excuse me when I say that his description of the phenomena of serum disease in man requires amplification. For example, he does not mention the circinate rash, which is next most common to the urticarial, and he says that the morbilliform rash is sometimes, but more rarely seen than the urticarial. As a matter of fact, nowadays the morbilliform rash bears no such comparison, for it is rare.

I am, Sir, yours faithfully,

FREDERIC THOMSON.

North-Eastern Hospital, Tottenham, N., Jan. 22nd, 1917.

*To the Editor of THE LANCET.*

SIR.—I have often wondered whether, in the case of severe immediate reaction of anaphylaxis, sufficient attention is given to the possibility of swelling of an urticarial type

in the larynx. A patient suffering from diphtheritic laryngitis was admitted to hospital under my care. Tracheotomy was performed and antitoxic serum given subcutaneously. The tube was removed later. Recovery was slow. Following on a treatment which was then being given trial, a second injection of serum was given about six weeks after the admission of the patient to hospital. Within a few minutes of the injection the patient (a small boy) developed an extraordinarily severe urticarial rash in practically all regions. At the same time typical signs of laryngeal obstruction were seen and the boy became very cyanosed. The tracheotomy wound was reopened and a tube inserted. All respiratory embarrassment disappeared at once. The simplest explanation seemed to be that the urticarial rash had extended to the larynx.

I should therefore certainly try the effect of tracheotomy if in a severe immediate reaction, accompanied by urticaria, a fatal result was threatening.

I am, Sir, yours faithfully,

Jan. 20th, 1917.

MILES B. ARNOLD.

### DEFINITION OF ACUTE ALCOHOLISM.

*To the Editor of THE LANCET.*

SIR.—I have read with interest Dr. W. O. Sullivan's letter on this subject in your issue of Jan. 20th and I gladly supplement the data of my original letter in the direction desired. I fear, however, that I can give no explanation of the curious paradox that the police figures for the Edinburgh area show an apparent material decrease of drunkenness among women, while the admissions into my wards of women suffering from acute alcoholism have more than doubled. This paradox is all the more remarkable because the conclusion indicated by the hospital figures, as to the great increase of drunkenness among women, is confirmed in the experience of the officials of the out-patient department where minor cases of alcoholism are dealt with, and also by all the collateral evidence obtained.

In reply to one query of Dr. Sullivan's, I may say that there has been no marked alteration in the type, and no change in classification, during the five years in which the wards in question have been under my care.

I have not looked into the point whether there has been any special change observed in the incidence of frankly declared delirium tremens. I attach little importance to this point. Delirium tremens is merely an incident in the development of some cases of acute alcoholism. I should say it is observed in from one-third to one-half of the cases admitted, the former figure being probably the more correct. By way of illustration, I may say that since reading Dr. Sullivan's letter I have taken the last ten cases of alcoholism admitted to my wards, since the 10th of this month, eight of which were brought in by the police; two of these only developed any symptoms of delirium tremens.

My experience leads me to doubt whether statistics of delirium tremens can be regarded as a useful and reliable means of gauging alcoholism in England; if the figures of the Royal Infirmary may be taken as typical of the rest of Scotland, I am satisfied they would not form a complete and reliable guide to sobriety in Scotland.

I am, Sir, yours faithfully,

Edinburgh, Jan. 22nd, 1917.

CHALMERS WATSON.

### A PLEA FOR THE GENERAL USE OF PNEUMATIC TOURNIQUETS.

*To the Editor of THE LANCET.*

SIR.—The usual method of arresting the circulation in the forearm and hand or the leg and foot during operations on these extremities by winding a tightly stretched piece of elastic tubing round the arm or thigh over a layer of gauze has certain disadvantages. The assistant may fail to apply the tourniquet with sufficient tightness to arrest the circulation, or, more often, the tube is applied with some roughness and so as to exert an unnecessary degree of compression. I have seen disappearance of the radial pulse persist for several days after the use of such a tourniquet on the arm of a young adult. The rubber tube must be applied before the towels are arranged and often some minutes before the first incision is made, and its release towards the close of the operation is often an inconvenient business. If vessels

and nerves can be injured by this procedure in a young healthy subject, how much more serious is the danger in old patients with diseased and brittle arteries. Perhaps the occasional recurrence of gangrene in the flaps of an amputation undertaken for diabetic gangrene is due in no small measure to injury and thrombosis of the main artery at the site of the tourniquet.

The ordinary sphygmomanometer makes an excellent pneumatic tourniquet for use in operations below the middle of the thigh or arm. The pneumatic armlet is applied to the upper part of thigh or arm and the pressure raised and maintained for a moment to ensure that the apparatus does not leak. The administration of the anaesthetic is begun, the limb is raised to empty the veins, and the sterile towels arranged. When the surgeon is about to begin the armlet is inflated till 5 mm. of mercury above the maximum systolic pressure is registered by the manometer. A spring clip may then be applied to the tube coming from the inflating bulb to guard against any leakage through its valve. When the main vessels have been ligatured the pressure can be instantly lowered to enable the recognition of fine bleeding points, or as instantly raised again should the hemorrhage be too free. A bicycle pump can be substituted for the usual inflating bulb with advantage.

To arrest the circulation at the level of the hip or the shoulder a special pneumatic band has to be constructed, but for the greater number of amputations or other operations on the extremities the ordinary sphygmomanometer, which is in the armamentarium of most doctors, suffices. Such a pneumatic tourniquet has the following advantages :—1. No violence can be caused by its application. 2. Only the minimum pressure required is employed. 3. The tourniquet can be brought into action or released easily and instantaneously and so need not be in force for a second longer than is necessary.

I am, Sir, yours faithfully,

KENELM H. DIGBY, M.B., B.S. Lond., F.R.C.S. Eng.,  
Ho Tung Professor of Clinical Surgery, University of  
Nov. 27th, 1916.  
Hong-Kong.

### THE CAUSE OF TRENCH-FOOT.

*To the Editor of THE LANCET.*

SIR.—If wetness, leading to electrical changes, were the cause of trench-foot, as suggested by Mr. Nepean Longridge in your issue of Jan. 13th, warm water should cause the condition as much as cold water. Now, anybody who has observed rice-growing and waterside communities in the tropics will know that they do not suffer from trench-foot, though their feet are constantly wet.

I am, Sir, yours faithfully,

V. T. CARRUTHERS,  
Captain, R.A.M.C.

### THE TREATMENT OF TRENCH-FOOT.

*To the Editor of THE LANCET.*

SIR.—The experimental work of Lorrain Smith, Ritchie, and Dawson on rabbits suggests that in the affection known as trench feet the primary and most serious injury is sustained by the blood-vessels. They found in their experiments that the vessel walls had been seriously damaged; there was swelling of the intima and vacuolation of the cells of the muscle coat. There was also considerable exudate and the establishment of a condition of local stasis and oedema.

A large number of cases of trench feet have come under my care, and I have been struck by the fact that nearly all these patients complained of the pain which they endured at night. This symptom, combined with the obvious signs of local vaso-motor paralysis, led me to try the effect of affording external support to the relaxed vessels by means of crêpe bandages. In every case the relief from pain has been striking and immediate, and the progress of cases so treated has been rapid and satisfactory. The bandages should be applied so as to exert a firm but gentle pressure without causing constriction of the vessels, and, as a matter of practice, most patients speedily learn to adjust them for themselves. The entire foot should be bandaged, and the toes can best be included by first enclosing them in cotton-wool. If small patches of broken or ulcerated skin are present the bandages can be applied over the ordinary dressing.

This method of treating trench feet by crêpe bandages will be found most valuable in at once alleviating the pain which is so common a feature of this condition, and, while directly promoting the absorption of exudates, it has the advantage that it need not interfere with any of the usual methods of treatment by massage or electricity.

I am, Sir, yours faithfully,

GEORGE COOPER, B.A., M.D.,  
Medical Officer in charge of Electro-therapeutic Department,  
Jan. 20th, 1917. Royal Victoria Hospital, Netley.

## MUNITION WORK AND CHILD WELFARE.

*To the Editor of THE LANCET.*

SIR.—In common with other districts throughout the country we have been making special efforts during the past few years for the improvement of child welfare and the protection of infant life. Much good has undoubtedly been done, but disappointment has been met with at times, and I have been impressed lately by the fact that munition work is becoming responsible in many cases for home neglect. This can hardly fail to follow if, as seems to happen frequently, the mother as well as the older daughters of a family spend the day at a munition factory. There is a large factory near here which offers tempting wages to every woman capable of work, and in some families, at any rate, the mothers of small children, together with the older girls, are now working there daily, leaving the younger children, including babies, to the care of girls, or even boys, of from 12 to 14, or to the casual charge of neighbours. The remedy would seem to be that before engaging mothers of families at munition works inquiry should be made, and that the mother should not be engaged unless she can show that some responsible woman is in charge of the children. Munition work is, of course, all-important, but if it be carried on at the expense of the young children of the nation the balance might work out ultimately on the wrong side. From a national point of view the mother's most important work is with her children.

I am, Sir, yours faithfully,

H. CAMERON KIDD,  
Jan. 11th, 1917. Medical Officer of Health of Bromsgrove.

## THE PREVENTION OF VENEREAL DISEASE.

*To the Editor of THE LANCET.*

SIR.—Your remarks upon this subject in the leading article in THE LANCET of Jan. 13th are of great practical moment. In venereal disease prevention is the treatment, as very few cases are actually cured. Time and money fail the sufferers, and so these pass into chronic states.

In 1907 I inquired into the German system of prevention, and after much trouble I obtained reliable information. It may be of interest now, and also a practical lesson to us, to state that in 1911 I wrote to the English consul in a leading German city asking him to find out all the facts relating to venereal prevention. He replied that he had inquired in "several competent quarters," and that he was "assured by naval officers of high standing that they knew nothing of such a system"! What ignorance! In 1912 I produced a small case containing drugs to prevent gonorrhoea, chancroid, and syphilis, spending about £50 upon this outfit. My idea was that the shipping companies would take it up, and—after the German plan—fix a slot machine, with the little tin cases inside, so that each seagoing man before going ashore could, by dropping in 1s. or less, obtain a reliable supply. I still hope that such slot machines will be fixed on each ship and at the various sailors' homes and other places.

When I was requested by the Liverpool S.S. Owners' Association to draft a report for presentation to the Venereal Commission, I described fully the system of prevention in various countries. This report was sent to the Commissioners, and also several of the little tin preventive boxes. I regret the Commission did not recommend this suggestion. It is instructive—in this commercial country—that when I attempted to advertise it in so many of the medical and lay papers all refused to insert it! Now that "Mr. and Mrs. Grundy" have been suffocated, I am glad to see that my pioneer work is bearing practical results. The German system makes a marked mistake in attacking this big question from the male side

only. The female must be taken in hand also, especially as it is now recorded that in certain U.S.A. (and other) cities the female prostitute is known to have not less than 30 male prostitutes *daily* having sexual relations with her. We are at the beginning only of this great national question of prevention of venereal diseases, and prevention is almost the only rational programme to adopt. It will give the best results of all.<sup>1</sup>

I am, Sir, yours faithfully,

Liverpool, Jan. 20th, 1917. ROBERT R. RENTOUL.

## THE NOMENCLATURE OF "INTERNAL SECRETION."

*To the Editor of THE LANCET.*

SIR.—Dr. Blair Bell adopts a method of controversy in which I cannot compete with him. I am content to let such epithets as "back-handed," "arrogant," and "vain-glorious" recoil upon the person who employs them.

I am, Sir, yours faithfully,

Edinburgh, Jan. 23rd, 1917. E. A. SCHÄFER.

## THE OFFICIAL VISIT TO THE FIELD BUILDING.

*To the Editor of THE LANCET.*

SIR.—You will have seen a report published in the *Times* that my private room in the *Field* building had been officially visited under warrant from the War Office. Will you kindly grant me space to say briefly that this visit had no relation to any business of the *Field* newspaper and concerned only correspondence relating to a high explosive in which I am privately interested? I have stated the whole case in a long letter which the *Times* was good enough to print for me on Jan. 18th.

I am, Sir, yours faithfully,

THEODORE A. COOK.

Windsor House, Bream's-buildings, E.C., Jan. 18th, 1917.

## MASSAGE AND MEDICAL ELECTRICITY IN THE AFTER-TREATMENT OF CONVALESCENT SOLDIERS.

*To the Editor of THE LANCET.*

SIR.—I should like to emphasise particularly the efficacy of the following simple applications in the after-treatment of convalescent soldiers.

1. *Ionisation.*—Many of those cases in which the passage of shrapnel or bullets through a limb has produced considerable disorganisation of tissue, with resulting pain, stiffness, and weakness, are very greatly benefited by ionic medication. As a rule, sodium ions are useful for softening large hard scars, and iodine ions help in the absorption of fibrous masses; but in view of the fact that one often finds conditions suggestive of a slow infective process salicylic acid can often be employed with advantage as the ionising drug. A preliminary application of radiant heat will undoubtedly assist ionisation in many instances.

2. *Spinal galvanism.*—For a number of men suffering from the nervous irritability, hypersensitiveness, and indefinite muscular pains which are not infrequently met with in the convalescent stages of war neurasthenia, the descending galvanic current applied with the anode over the cervical spinal region and each foot placed in a small bath, and the baths both connected to the negative pole, gives excellent results. I have been struck by the way in which the men themselves have spoken appreciably of this treatment, which may be varied by using a combined galvano-faradic (or galvano-sinusoidal) current.

3. *Statio electricity.*—For the treatment of shell shock after the initial stages I cannot speak too highly of the static apparatus. Where there are irritability, restlessness, disturbed sleep, and headache, I have found simple charging—with the patient on an insulated platform connected to the negative pole whilst an electrode is adjusted to give a gentle head-breeze—an invaluable method.

May I also point out the desirability of medical men in general practice keeping in touch with various electro-

<sup>1</sup> Those practically interested will find a reference to systems in force in my essay, *The Prevention of Venereal Diseases* (Booksellers Co., 72, Ford-street, Liverpool, 2s. Id.).

therapeutic measures that are being successfully carried out in the treatment of the convalescent wounded, for it is certain that they will ultimately have to deal with a number of cases requiring treatment of this kind and it will be most unfortunate if these drift into the hands of unqualified "medical elec ricians."

I am, Sir, yours faithfully,

EDWIN L. ASH, M.D. Lond.,

Physician and Neurologist to the City of London  
Harley-street, W.  
Red Cross Hospital.

## THE LOCALISATION OF FOREIGN BODIES.

To the Editor of THE LANCET.

SIR.—In the hope that it may prove of use to anyone similarly situated to myself I venture to enclose a brief description of an adaptation of the Mackenzie-Davidson principle of localisation of foreign bodies which I devised for my own use. My X ray apparatus, which is one ordered by the Civil Administration of the Nyasaland Protectorate, was not equipped with a localiser of any description, and as there are practically no facilities for elaborate workmanship in Central Africa my own model is naturally rather a crude article.

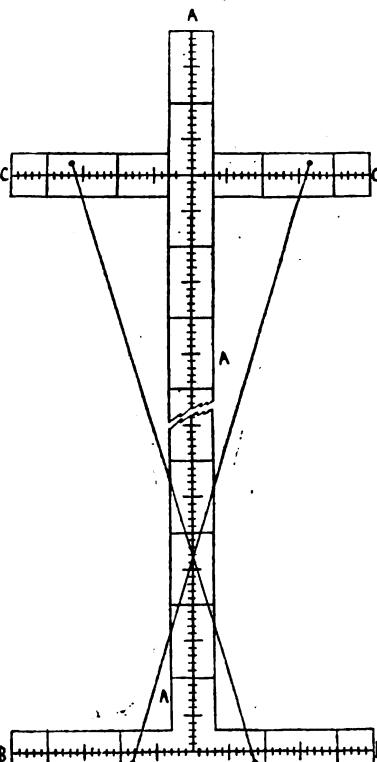

The apparatus is shown in the accompanying figure. It consists of a length of hard wood, A, 3 feet long, graduated on the face in inches and, or, centimetres. At the lower end is fixed a crossbar, B, 18 inches long, at right angles to A, and similarly graduated. A similar crossbar, C, is arranged to slide on A over its entire length. The centre line of B represents the plane of the X-ray plate, and that on C represents the plane of the tube-anticathode. After marking the skin directly over the incident ray by any of the usual methods, move the tube—say 3 inches—to the left of the centre position and expose the plate; then move the tube 3 inches to the right of the centre position—that is, 6 inches in all—and make a second exposure on the same plate, thus obtaining two shadows of the foreign body on the one plate. Now set the centre line of crossbar C at a distance from the centre line of crossbar B equal to the distance of anticathode from the plate. Measure the distance between the two shadows on the plate—say this is 3 inches. Now by setting the two threads on C from 3 inches to the right and left of the centre line of A, representing the traverse of the tube, to 1½ inches to the left and right of the centre line of A on B, representing the distance between shadows, the depth from the plate, of the foreign body can be read off direct by noting where the threads cross the centre line of A. The threads shown in the figure are fastened by means of drawing-pins.

This method will be found simple, rapid, and sufficiently accurate for all but the most delicate of work. The illustration is not drawn to scale, but will serve to illustrate the principle of operation.—I am, Sir, yours faithfully,

PERCY PERROW,

Lieutenant, S.A.M.C.; Radiologist, Nyasaland Field Force.

Dec. 8th, 1916.

## The War.

### THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

#### Died.

Surgeon C. E. Reckitt, R.N., was a student at Guy's Hospital, London, and qualified in 1913. He had held appointments at Guy's and at the Royal Infirmary, Hull.

#### Wounded.

Capt. F. B. Simpson, R.A.M.C.

Capt. W. D. Reid, R.A.M.C., attached Manchester Regiment.

Capt. C. M. Forster, R.A.M.C., attached Yeomanry.

### THE HONOURS LIST.

The following promotions of and awards to medical officers are announced:—

#### G.C.B.

Surg.-Gen. Sir A. Keogh, K.C.B. (ret. pay).

#### K.C.B.

Surg.-Gen. W. Donovan, C.B. (ret. pay); Col. (temp. Surg.-Gen.) N. H. Howse, V.C., C.B., Australian A.M.C.

#### C.B.

Surg.-Gen. W. W. Kenny (ret. pay); Col. E. North (ret. pay). A.M.S.; Col. W. H. Horrocks, A.M.S.; C. I. D. J. MacKintosh, M.V.O., A.M.S. (T.F. Res.); Col. C. C. Reilly, A.M.S.; Col. J. Thomson, A.M.S.; Surg. Lt.-Col. P. J. Freyer, ret'd, I.M.S.; Lt.-Col. T. H. Openshaw, C.M.G., R.A.M.C. (T.F.); Lt.-Col. H. G. Barling, R.A.M.C. (T.F.); Lt.-Col. H. Davy, R.A.M.C. (T.F.); Temp. Lt.-Col. Sir T. Myles, R.A.M.C.; Temp. Lt.-Col. Sir W. A. Lane, Bart., R.A.M.C.; Temp. Lt.-Col. J. Swain, R.A.M.C.; Temp. Lt.-Col. W. A. Turner, R.A.M.C.; Temp. Lt.-Col. Sir B. G. A. Moynihan, R.A.M.C.; Temp. Lt.-Col. (temp. Col.) R. Jones, R.A.M.C.

#### K.C.M.G.

Surg.-Gen. G. D. Bourke, C.B. (ret. pay).

#### C.M.G.

Lt.-Col. W. W. Pope, late R.A.M.C.; Lt.-Col. G. E. Twiss (ret. pay), late R.A.M.C.; Lt.-Col. H. E. B. Bruce-Porter, R.A.M.C.; Lt.-Col. G. B. Stanisic, R.A.M.C.; Lt.-Col. (temp. Col.) R. S. H. Fuhr, D.S.O., R.A.M.C.; Lt.-Col. (temp. Col.) H. P. W. Barrow, R.A.M.C.; Temp. Hon. Lt.-Col. J. L. Thomas, C.B., R.A.M.C. (Maj. ret. T.F.); Maj. G. L. Guilland, R.A.M.C.; Col. Hon. W. B. Collins, New Zealand Medical Corps.

#### To be Brevet Colonels.

Lt.-Col. H. A. Baines, R.A.M.C.; Lt.-Col. C. J. Jaomb-Hood, 2nd Easter General Hospital, R.A.M.C. (T.F. Res.).

#### To be Brevet Colonel on R-tred List.

Lt.-Col. A. W. Browne (ret. pay), late R.A.M.C.

#### To be Brevet Lieutenant-Colonels.

Maj. (temp. Lt.-Col.) B. A. Craig, R.A.M.C.; Maj. F. McLennan, R.A.M.C.; Maj. (temp. Lt.-Col.) A. H. Safford, R.A.M.C.; Maj. (temp. Lt.-Col.) C. R. S. Bradley, R.A.M.C., commanding Training Centre.

#### To be Brevet Majors.

Capt. A. E. G. Fraser, R.A.M.C.; Capt. (temp. Maj.) B. W. D. Leslie, R.A.M.C.

#### Military Cross.

Capt. H. V. Stanley, R.A.M.C.

### MENTIONED IN DESPATCHES.

Lieutenant-General the Hon. J. C. Smuts, K.C., Commander-in-Chief of the East African Forces, in a lengthy despatch dealing with the campaign in East Africa since March last, says: "The work of the medical units has been very heavy, and all ranks have done their utmost in their care of sick and wounded, and in arranging for their speedy evacuation."

### OBITUARY OF THE WAR.

#### RODERICK CAMPBELL MCLEOD, M.D. NEW YORK, LIEUTENANT-COLONEL, CANADIAN ARMY MEDICAL CORPS.

The death of Lieutenant-Colonel R. C. McLeod occurred at Bramshott Camp, Jan. 4th, under conditions both tragic and startling. He succumbed, after 24 hours' illness, to an anthrax infection communicated by a shaving-brush through a trifling razor abrasion on the face. Colonel McLeod was a Nova Scotian, a Scotch Highlander by extraction and very near in instincts and character to the parent stock. He was born in Cape Breton Island in 1867 and practised his profession in his native island. In December, 1915, he gave up his private work and went to Halifax to offer himself to the Canadian Army Medical Corps. When the University of St. Francis Xavier, a Catholic University in Nova Scotia, proposed offering a medical unit to the Government, he was selected to forward the project and afterwards to command the unit. It was known as No. 9 Stationary Hospital, C.E.F. In October of last year Colonel McLeod, with his unit, took charge of Bramshott Military Hospital, and to the discharge of this duty he was giving his best endeavours when the fatal accident occurred.

**DEATHS AMONG THE SONS OF MEDICAL MEN.**

The following sons of medical men must be added to our lists of those who have fallen during the war:—

**Private W. N. Archibald**, Royal Fusiliers, elder son of Major W. N. Archibald, R.A.M.C.  
**Capt. L. Porter**, Royal Flying Corps, son of Capt. D. Porter, R.A.M.C.  
**Capt. O. C. Ward**, Indian Infantry, second son of the late Major E. C. R. Ward, R.A.M.C.  
**Private P. B. Barlow**, Grenadier Guards, youngest son of Sir T. Barlow, Bart., K.C.V.O., late President of the Royal College of Physicians of London, of Wimpole-street, London.  
**Surgeon C. E. Reckitt**, R.N., elder son of Colonel J. D. T. Reckitt, R.A.M.C.

**RED CROSS WORK IN THE COUNTY OF LONDON.**—The December report of the work done by the London Divisions of the Red Cross Society makes very satisfactory reading, though there is still need for more adequate provision for training in Red Cross subjects. Of 112 candidates examined during the month 26 failed in first-aid, 22 in home nursing, and 2 in hygiene and sanitation, the greater number of passes being in first-aid—namely, 273. Owing, perhaps, to press of work, local secretaries do not in some cases supply their reports as promptly as the smooth working of the organisation demands. To meet this and other difficulties arrangements are being made to inspect systematically the work of each division.

**THE WELFARE OF WOMEN WORKERS.**—At the Mansion House on July 22nd the Lord Mayor presided at a meeting organised by the Young Women's Christian Association with the object of providing rest and recreation huts for women employed in munition works. Dr. Addison, in appealing for funds, said that Feb. 27th would be a Woman's Day in London, and he hoped that the large sums of money which were much needed for the work which the Young Women's Christian Association was organising would be forthcoming. It had been proved, he said, that there were few occupations that women were not capable of entering and already 900,000 women were acting as substitutes for men in the industrial work of the country, 500,000 being engaged in the production of munitions, a number which was increasing by 34,000 a month. He believed that the work undertaken by the Young Women's Christian Association, properly handled and wisely administered, would provide a basis for an organisation that would endure after the war and come to be regarded as an essential concomitant of our industrial life.

**SCOTTISH WOMEN'S HOSPITALS: CALCUTTA UNIT.**—As a result of a collection inaugurated on St. Andrew's Day a donation of £13,000 has been sent from Calcutta to the offices of the Scottish Women's Hospitals, 2, St. Andrew-square, Edinburgh, for the equipment and maintenance of a Calcutta unit.

**REST-HOUSE FOR SAILORS AND SOLDIERS.**—Major-General Sir Francis Lloyd, in opening the St. Peter's Rest House for Soldiers and Sailors on Jan. 22nd at 4, Eccleston-square, S.W., referred to the difficulties of the authorities in finding accommodation for sailors and soldiers derelict in London, and paid a warm tribute of praise to the public institutions which had provided the necessary accommodation. Societies such as the Young Men's Christian Association, the Church Army, and the Salvation Army have now made available nearly 10,000 beds for men coming from the front.

**THE SUPPLY OF WINE TO THE FRENCH SOLDIER.**—It is stated that the French Government has requisitioned for the purposes of the Army a very substantial proportion of the vintage production. In France, therefore, wine has assumed a military importance, for no less than 200,000,000 gallons of wine from the country, together with 40,000,000 gallons from her Algerian colony, have been reserved for the use of the soldier. It would appear that each officer and man receives daily half a litre of wine. This allowance has been adopted since the war began, and the authorities are convinced that it has contributed to the health and efficiency of the troops through a campaign conducted under very trying conditions. The reasonable consumption of the wine of the country (*ein ordinaire*) is evidently regarded as beneficial rather than demoralising.

**Obituary.**

**DUNCAN BURGESS, M.A., M.B. CANTAB., F.R.C.P. LOND.,**  
 PROFESSOR OF MEDICINE IN THE UNIVERSITY OF SHEFFIELD AND  
 CONSULTING PHYSICIAN TO THE SHEFFIELD ROYAL INFIRMARY.

We regret to announce the death of Dr. Duncan Burgess, which took place at his residence in Sheffield on Jan. 17th.

Born at Grantown-on-Spey in 1850, Duncan Burgess received his early academic training at the University of Aberdeen, where, at an early age, he took the degree of Master of Arts. Proceeding to Cambridge, he became 13th Wrangler in 1875, and later was elected a Fellow of Corpus Christi College. Adopting then a medical career, in 1882 he became M.B. Cantab., obtaining, five years later, the Membership, and in 1905 the Fellowship, of the Royal College of Physicians of London.

He came to Sheffield in 1887, and was for many years physician to the Sheffield Royal Hospital, retiring as senior physician on reaching the age-limit in 1915. At Sheffield he occupied a prominent place in the academic world. He was for a long period lecturer on medicine at University College and later became professor of medicine in the University, while he was for some years the energetic secretary of the Sheffield Medico-Chirurgical Society. In 1890 he was deputed by the society, with Dr. W. S. Porter, to visit Germany and report on Koch's tuberculin treatment, and in 1899 was President.

At the outbreak of war he was mobilised with the rank of Lieutenant-Colonel, and acted for nearly two years as officer in charge of the Medical Section of the 3rd Northern General Hospital (T.F.). There is no doubt that the arduous work in connexion with his military duties brought on the fatal illness.

A personal friend writes:—

By the death of Dr. Duncan Burgess the profession in Sheffield has lost a loyal friend and an able and gifted colleague. To the younger men in the profession he never failed when the opportunity arose to hold out a helping hand. To all he was genial and kindly, and he succeeded in winning the affection in no small measure of patients and colleagues alike. In his profession a deep reader and keen critic, beyond it he possessed a wide knowledge of literature and a sympathetic interest in men and affairs. A great raconteur, a great lover of his native Scotland, an ideal host—for these things, hardly less than for his professional attainments, he was esteemed by those who knew him.

**GEORGE MUNRO SMITH, M.D. BRISTOL (HON. CAUSA)**  
 LIEUTENANT-COLONEL, R.A.M.C. (T.); CONSULTING SURGEON TO  
 BRISTOL ROYAL INFIRMARY.

Dr. Munro Smith, who died at his home in Clifton on Jan. 13th after a long and painful illness, was in his sixty-first year. He was the son of a surgeon, and was educated at Clifton College and University College, London, returning to Bristol after obtaining the Conjoint Board qualification, where he was in succession medical tutor, demonstrator of physiology, and demonstrator of morbid anatomy. In 1893 he accepted the chair of physiology at Bristol University College, and in this capacity was one of the pioneers in the formation of the University of Bristol, which recognised his services by making him honorary M.D. in 1912. From 1883 he occupied public surgical posts, first at the Orthopaedic Hospital, then at the Royal Infirmary, where he became full surgeon in 1897, and Clifton Dispensary. Outside his many teaching appointments Dr. Munro Smith was active as President of the local branch of the British Medical Association, of the Bristol Naturalists' Society, and for a time of the Medico-Chirurgical Society. His many-sided career brought him into intimate relation with his colleagues, among whom, and especially the undergraduates, he was a popular figure.

**THE LATE MR. C. M. BRADY.**—Mr. Charles Matthew Brady, L.R.C.S.I., who died with tragic suddenness on Jan. 19th on his way to the Wigan Infirmary, where he was consulting surgeon, was one of the best known medical men in the Wigan district. After qualifying in Dublin he was for a short while in practice in Oxford before making his home for 35 years in the Lancashire manufacturing town. Mr. Brady was a member of the Borough Insurance Committee and sat for some years on the School Board. He was aged 62 years and leaves a widow and three children.

## Medical News.

**ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH,  
ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL  
FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.**—  
The examinations of this Board were concluded at Edinburgh  
on Jan. 20th, with the following results:—

### FIRST EXAMINATION.

Sayed Chaleb and Arthur Henry Jacobs.

*Physics.*—Catherine Millar, John Morrison McCubbing, Alexander Clon Thom, Robert Charles Dow, James MacClashan, and John Lister Redcliffe Ross.

*Biology.*—Robert Charles Dow.

*Chemistry.*—John Morrison McCubbing.

### SECOND EXAMINATION.

Andrew Wood Smith, Gwilym ap Vychan Jones, Thomas Richard O'Keeffe Alexander Forsyth Caddell, George Michie Raeburn, Norman Joseph Patterson, Thomas Hall James Douglas, and Jagindra Kumar Sen.

*Anatomy.*—Robert Berry Forgan, Janet Adeline Agnes Sang, Lizzie Robertson Clark, and Thomas Arnoldus du Toit.

*Physiology.*—William Harvie Kerr and Walter Granville Carew.

### THIRD EXAMINATION.

Hugh Emile Colman Collins, William O'Gorman Donoghue, Cecil Stuart Baxter, Andrew Francis Brighten, Hassan Amin Madwar, John Kohler Steel, and Arthur Stanley Hughes.

*Materia Medica.*—Eduard Louis Adendorff, John Vaughan Griffith, Jung Bahadur Singh, Thomas Blaney, and John Haldane Bain.

### FINAL EXAMINATION.

The following candidates having passed the Final Examination were admitted L.R.C.P. Edin., L.R.C.S. Edin., L.R.F.P. & S. Glasg.:—

William Fidler Mason, John Alexander Tolmie, James Wallace Gordon, Robert Frederick Claude Hamilton Buchanan, Alfred Black, Yeshwant Narayan Kadam, John Berry, Alfred David Gorman, and Wendell Thomas Garretson.

*Medicine.*—Russell Nelham Burton, Frederick Joseph Jack, Mary Gray Jones, and Jackson Baird Minford.

*Surgery.*—Don Adrian Jayasinghe.

*Midwifery.*—Benjamin Ajayi-Young, Robert Cloag Battersby, Alfred Edwin Elliott, Frederick Joseph Jack, and George Alexander Grandsoult.

*Medical Jurisprudence.*—Albert Ernest Hempleman, Allan Paul McLeod, Robert Pollok, Joseph Michaelson, Arukatti Patabendige Frederick Abeyasuriya, John Lavens West, Andrew Inglis Meek, Donald Stewart, Frederick Joseph Jack, and Daniel Cornelius Howard.

IN order to increase the amount of barley, sugar, and other brewing ingredients available for food, Lord Devonport has proposed a further restriction of the output of beer to 70 per cent. of the present output, that is to say, to 50 per cent. of the pre-war figure. The War Cabinet has approved the proposal, and decided on a corresponding restriction on the release of wines and spirits from bond. A Bill confirming this decision will be introduced in the coming session of Parliament.

A SPECIAL introductory medical course in physics, chemistry, and biology for students desirous of beginning their medical studies will be held at University College, London, and will begin on March 1st. Intending students should communicate forthwith with the secretary, University College, Gower-street, London, W.C.

THE Council of the London and Counties Medical Protection Society, Ltd., at their meeting on Jan. 17th, decided to apply for £9,500 £5 per cent. War Loan (£2100 new money), bringing the amount of the society's investment in war securities up to £10,000.

**ROYAL SOCIETY OF ARTS.**—On Tuesday afternoon next, Jan. 30th, a paper on Imperial Industries After the War will be read by Mr. Octavius C. Beale, Representative and Past-President of the Australian Associated Chamber of Manufacture, to the Colonial Section of the Society. The chair will be taken at 4.30 o'clock by Mr. Long, Secretary of State for the Colonies.

**CENTRAL MIDWIVES BOARD.**—A meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on Jan. 18th, with Sir Francis H. Champneys in the chair. Correspondence was considered with the matron of an institution recognised by the Board as a training school for midwives with reference to the examination schedules of two candidates on whose behalf she had signed the certificates of training certifying that they had undergone a course of training in midwifery extending over a period of six months, when in fact their training had then extended over a period of less than five months, as she well knew. The Board decided that the institution be informed that the Board takes a very serious view of the signing of untruthful certificates; that in the present case there is no question that the action of the matron was due to an "oversight" or that "it was unintentional"; that the Act of Parliament (Sect. XII.) provides penalties

of 12 months' hard labour for this offence; that the offence is aggravated by the fact that the institution is one from which the Board might have expected a high standard of honour; that the Board, in view of the gravity of the offence, postpones judgment until its next session.—A letter was considered from the town clerk of Middlesbrough enclosing a copy of a communication addressed by the coroner of Middlesbrough to the medical officer of health, stating that at an inquest held by him on Oct. 12th, 1916, on the body of a new-born child, the jury had added a rider to their verdict expressing the view that a midwife should not be allowed to notify as stillborn a child born before her arrival in a case where no registered medical practitioner was in attendance at the time of birth. The Board decided that the town clerk of Middlesbrough should be thanked for his letter, and be informed that the Board has noted the suggestion conveyed in the rider of the coroner's jury for consideration on the next revision of the Rules.—At a special meeting of the Central Midwives Board held on Jan. 19th, a number of midwives were struck off the Roll for various charges.

**CENTENARIANS.**—On Jan. 17th, the 100th anniversary of his birth, Mr. David Lewis, a liveryman and pensioner of the Glaziers' Company and the oldest City pensioner, was presented by the Company with a framed and illuminated copy of a resolution of congratulations passed by the Court at its last meeting, together with a gift of one hundred crowns. Mr. Lewis, who lives at Seven Kings, enjoys good health.—The King has sent a telegram of congratulation to Mrs. Arthur Mozley, of Malvern View, Cheltenham, who has completed her 102nd year.—Mrs. Ann Morrison, of Gairloch, has just completed her 103rd year.

**MEMORIAL TO THE LATE MR. R. L. SWAN.**—A committee has been formed to collect subscriptions to found a memorial to the late Robert L. Swan, Past-President of the Royal College of Surgeons in Ireland, and for many years surgeon to Dr. Steevens' Hospital and to the Orthopaedic Hospital. The latter institution he helped to found in 1876. The precise form of the memorial has not yet been decided upon, but it is intended that it should be associated with the two institutions to which he had devoted so much of his life. The honorary secretary and treasurer of the memorial fund is Dr. T. Percy C. Kirkpatrick, of 11, Fitzwilliam-place, Dublin.

## Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

**CAMPBELL, MALCOLM, M.D. Glasg.**, has been appointed Medical Officer of Health for Droitwich.

**GALE, A. K., L.R.C.P., M.R.C.S.**, Consulting Medical Officer, and **LUTHER, S., Assistant Resident Medical Officer** to the Coalbrookdale Bierlow Union.

**HARRIS, H. G., M.D. Durh.**, one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No 51.

**JACKSON, W., M.D. Brux.**, F.R.C.P.S. Glasg., Medical Officer for the Nelson Medical District by the Burnley Board of Guardians.

**PENNINGTON, LOUISE A.**, House Surgeon at the Wolverhampton General Hospital.

**PERRY, S. H., M.R.C.S., L.R.C.P. Lond.**, Temporary Medical Officer of Health for Spalding.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

**BARNESLEY, BECKETT HOSPITAL AND DISPENSARY.**—House Surgeon. Salary £200 per annum, with board, &c.

**BATH, EASTERN DISPENSARY.**—Resident Medical Officer. Salary £140 per annum, with furnished rooms, &c.

**BATH, WINSLEY SANATORIUM.**—Assistant Resident Medical Officer. Salary £250 per annum, with board, &c.

**BIRMINGHAM CITY.**—Female Doctor for Infant Welfare Work. Salary £350 per annum.

**BIRMINGHAM CITY EDUCATION COMMITTEE.**—Temporary Assistant School Medical Officer. Salary £300 per annum.

**BRISTOL GENERAL HOSPITAL.**—House Surgeon for six months. Salary at rate of £175 per annum, with board, &c.

**BRITISH RED CROSS HOSPITAL, Netley.**—Pathologist, Junior Operating Surgeon, and Radiographer.

**CAMBRIDGE, ADDENBROOKES HOSPITAL.**—Honorary Assistant Surgeon in Out-patients' Department.

**CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.**—Second House Surgeon. Salary £200 per annum, with board, &c.

**COVENTRY EDUCATION COMMITTEE.**—Temporary Assistant School Medical Officer. Salary £250 per annum.

**ESSEX, ADMINISTRATIVE COUNTY.**—Tuberculosis Officer. Salary £500 per annum.

**GRIMSBY AND DISTRICT HOSPITAL.**—House Surgeon. Salary £5 5s. per week, with board, &c.  
**HOSPITAL FOR SICK CHILDREN,** Great Ormond-street, London, W.C.—House Surgeon, Assistant Casualty Medical Officer, and House Physician, unmarried. Salary at rate of £60 per annum each, with board, &c.  
**EVAMINGTON SPA, WARWICKSHIRE AND SOUTH WARWICKSHIRE GENERAL HOSPITAL.** Second Resident Medical Officer. Salary £200 per annum, with board, &c.  
**NOTTINGHAM AND MIDLAND EYE INFIRMARY.**—Female House Surgeon. Salary £120 per annum.  
**PORTREE,** Island of Skye.—Parish Medical Officer and Public Vaccinator. Salary about £480 per annum.  
**ROYAL FREE HOSPITAL,** Gray's Inn-road, W.C.—Radiographer and Medical Electrician.  
**SCOTLAND, NAVAL AUXILIARY HOSPITAL.**—Assistant Surgeon and Medical Officer. Salary £1 per day, with board, &c.  
**SHEFFIELD UNION HOSPITAL, FIFVALE.**—Female Resident Assistant Medical Officer. Salary £250 per annum, with rations, &c.  
**STAFFORDSHIRE, WOLVERHAMPTON, AND DUDLEY JOINT COMMITTEE FOR TUBERCULOSIS,** MOXLEY SANATORIUM, near Wednesbury, Staffs.—Resident Medical Officer. Salary £350 per annum, with board, &c.  
**STANNINGTON, NORTHUMBERLAND, CHILDREN'S SANATORIUM.**—Female Resident Medical Officer. Salary £200 per annum, with board, &c.  
**SUNDERLAND ROYAL INFIRMARY.**—Female House Surgeon. Salary £150 per annum, with board, &c.  
**UNIVERSITY OF LONDON.**—External Examiners.  
**WEST HAM UNION SICK HOME,** 95, Forest-lane, Forest Gate, E.—Resident Assistant Medical Officer. Salary £300 per annum, with usual residential allowances.  
**WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.**—Resident Surgical Dresser.  
**WILTS COUNTY COUNCIL, GENERAL EDUCATION COMMITTEE.**—Assistant Medical Officer as School Oculist. Salary £360 per annum, &c.

**THE Chief Inspector of Factories, Home Office, London, S.W.,** gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Bridport, Dorset; Wells, Somerset; and Chester-le-Street, Durham.  
**THE Secretary of State for the Home Department, Whitehall, S.W.,** announces a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 4.

## Births, Marriages, and Deaths.

### BIRTHS.

**BARROW.**—On Jan. 4th, at Blahopton, Lochgilphead, Argyll, the wife of Surgeon Murray Barrow, R.N., of a son.  
**BROWN.**—On Jan. 12th, at Kasauli, Punjab, India, the wife of H. C. Brown, Major, I.M.S., of a daughter.  
**HALE.**—On Jan. 19th, at Cambridge-square, W., the wife of E. H. V. Hale, M.B., of a daughter.  
**KENDREW.**—On Jan. 16th, at Bedford-square, W.C., the wife of Mr. Dudley Kendrew, F.R.C.S., of a daughter.  
**WILSON.**—On Jan. 15th, at Rutherford-road, Balham, the wife of Maurice O. Wilson, Captain, R.A.M.C., of a daughter.

### MARRIAGES.

**NICHOLLS-BARRY.**—On Jan. 20th, at St. Margaret's, Westminster, T. B. Nicholls, Lieutenant-Colonel, R.A.M.C., to Margaret, eldest daughter of Walter Barry, of Sutton, Surrey.  
**SMYTHIE WOOD.**—On Jan. 16th, at the Parish Church, Clifton, Gerald Arthur Smythe, Captain, R.A.M.C., to Sarella Mary Mackenzie, third daughter of Mr. and Mrs. Robert Ley Wood, formerly of Cheltenham.  
**WICKRACK-HUNTER.**—On Jan. 17th, at St. Stephen's Church, Perth, Stanley Wickrack, M.R.C.S., L.R.C.P. Lond., Captain, R.A.M.C. (S.R.), to Mary Stewart, daughter of Mr. and Mrs. Robert Hunter, of St. John's, Perth.

### DEATHS.

**BURGESS.**—On Jan. 17th, at 442, Glossop-road, Sheffield, Duncan Burgess, M.B., F.R.C.P., aged 88 years.  
**HUGHES.**—On Dec. 18th, 1916, in Northern Assam, David E. J. S. Hughes, M.R.C.S., L.R.C.P. Lond., aged 30 years.  
**MEIKLE.**—On Jan. 22nd, at Edinburgh, Thomas Christopher Meikle, Fleet-Surgeon, R.N. (retired).  
**RECKITT.**—On Jan. 20th, at Royal Naval Hospital, Haslar, Charles Edward Reckitt, Surgeon, R.N., aged 30 years.  
**N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.**

### METEOROLOGICAL READINGS.

Other information which we have been accustomed to give in these "Readings" is withheld for the period of the war.

## Notes, Short Comments, and Answers to Correspondents.

### THE ORGANISATION OF THE MEDICAL PROFESSION FOR WAR.

WE have received from Mr. K. M. Beavis, B.A., assistant secretary to the National Medical Union, 346, Strand, London, W.C., the following statement on the instruction of the Chairman of the Council of the Union :—

In view of the somewhat alarmist and as they think misleading statements appearing in the press on the above subject, the Council of the National Medical Union at their meeting held on Saturday, Jan. 13th, considered the alleged difficulty in meeting the medical needs of the country, both civil and military. The term "mobilisation" in the sense of the suggestions so far made appears to be synonymous with the conscription of a particular body of citizens who are more than warned that any lack of spontaneous alacrity on their part in offering their services for disposal according to the wisdom of a certain Central Medical War Committee will be followed by compulsory legislation, and the ousting of native by imported foreign medical service so far as the civil population is concerned. Considering the whole-hearted response to the country's need which has characterised the medical profession in this crisis, a response which has frequently entailed much personal sacrifice, this attitude towards it by the powers that be seems neither just nor wise, nor has it, in the opinion of the Council of the National Medical Union, the justification even of necessity if a proper use be made of the medical material available. This union, whose opposition to the Medical Benefit Section of the National Insurance Act is well known, has no desire to snatch any advantage for its views on this occasion, but it expects a like self-abnegation on the part of those interested in the maintenance of the system of medical benefit referred to.

The Council of the National Medical Union, after full discussion and after consultation with cognate bodies in other parts of the Kingdom, believes that every medical need, civil and military, may be met on the lines and upon the conditions hereunder indicated, and which should be operative during the war and for a reasonable period thereafter until the situation is again tending to become normal and the abstract questions at issue in the medical world can again be considered. They believe also that medical services secured on these conditions will be willing services, a paramount consideration in the exercise of a profession in which physical ease has largely to be sacrificed and mental activity with much responsibility displayed and borne.

The conditions indicated to secure such services are as follows : 1. A primary condition to be repeal of the Medical Benefit Section of the Insurance Acts, thereby releasing many doctors who are unevenly distributed at present and releasing a population that would automatically distribute itself in the district. 2. Non-panel practitioners offering to attend the patients of panel doctors not to be required to attend them except as private patients.

The statement adds that the importation of English-speaking doctors to attend the civil population is totally unnecessary and not in the national interests, and that compulsion in the case of the medical profession will only lead to disaster.

The Council further concludes that any voluntary organisation should be carried out by a properly constituted medical committee elected by, and representative of, the profession.

### PILEWORT.

To the Editor of THE LANCET.

SIR,—In reply to Mr. F. W. Alexander's inquiry in your issue of Jan. 6th I have prescribed pilewort ever since Sir James Sawyer recommended it 16 years ago, and I cannot say it has ever failed me when properly applied. The preparation I use is that of a double cone suppository, made like an elongated dumb-bell, which is easily inserted and retained in position when grasped by both the internal and external sphincters until it is entirely absorbed. The suppositories must be made from the fresh plant, and are prepared by Messrs. Lowe and Co., Limited, 8, Stafford-street, Old Bond-street, W. Mr. Lowe informs me that it is only for about one month in the year that the plant is really active, and he thinks it is neglect of the old botanists' instructions, to "gather the plant only at the height of its short active life" that accounts for so many failures with it. Doubtless the introduction of a host of modern synthetic remedies has had a good deal to do with the neglect of this and other valuable old remedies.

I am, Sir, yours faithfully,

Jan. 20th, 1917.

MAYFAIR.

## THE CONSERVATIVE TREATMENT OF BURNS AND SCALDS.

To the Editor of THE LANCET.

SIR.—I am convinced from long experience in the treatment of burns and scalds that many deaths are caused from the excessive care in cleaning the wounds, which tortures the patient, and the subsequent application of painful applications. The waste of bandages is also appalling. The verdict "Died of shock from burns" I take to be the result in many cases of the long-continued pain received during the dressing. My own practice is to relieve pain with opium, morphine, cocaine, &c., and to get the patient to sleep as soon as possible. The great heat of either fire or water that caused the injury has acted as a thorough disinfectant to the clothing, which need not be removed but simply covered with cotton-wool. A few days later the wounds are easily made clean and free from clothes. Treated in this way I have never lost a patient who was burned or scalded.

I am, Sir, yours faithfully,

Catford, Jan. 18th, 1917.

G. J. O'REILLY.

## JAMAICA HEALTH REPORT.

IN the section of the report for 1915-16 of the Governor of Jamaica (Sir W. H. Manning, K.C.M.G., C.B.) devoted to vital statistics and public health it is stated that the estimated population on March 31st last was 894,735. The birth-rate for the year was 34.6 per 1000 and the death-rate 21.6 per 1000, as compared with 38.9 and 21.4 respectively in the previous year. 66.9 of every 100 births registered were illegitimate. This is slightly higher than the rate—66.8 per cent.—in 1914-15, which was the highest island rate recorded since the compulsory registration of births commenced in 1878. Of the total mortality with the births during the year, 30,854 infants were born and 7089 died at 1 year of age or under, equal to 22.9 per cent.; the percentage under 5 years was 26.9.

Owing to the inability to obtain salvarsan for use in the treatment of yaws, the travelling dispensary and hospital established in 1914 with a view specially to the treatment of this disease was closed on June 12th, 1915. During the time the dispensary was in operation 1498 patients were treated for yaws, 408 of whom received two injections and 60 three injections. Of the patients treated 1109 were cured, 4 died, and 385 were under treatment at the time of the closing of the dispensary. The number of cases of yaws treated with salvarsan in the several public general hospitals and medical districts was 637. The Legislative Council in March voted a sum of £2500 for the purpose of providing for the special treatment in Kingston of venereal diseases, which are very prevalent, and in some places, inclusive of Kingston, appear to be on the increase.

There were 5942 cases of hookworm treated with thymol at the various country hospitals, in addition to 123 cases among East India immigrants on the estates and 142 prisoners so treated at the General Penitentiary. At the latter institution the treatment of the infection by oil of chenopodium was tried, and the surgeon reports that the results clearly demonstrate that the oil is exceedingly powerful against both hookworm and the large ascaris, and that no ill effects after dosing were observed in any case. The opportunity was taken during the year of studying, by examination of the faeces bacteriologically, the effects of thymol, quassia, and oil of chenopodium on cases from other institutions, and establishing a comparison of the respective efficacies of these drugs. The Government bacteriologist, Dr. H. H. Scott, states that the conclusions to be drawn from these experiments are: (1) that quassia is of very little, if any, use against hookworm; (2) that thymol is not an ideal specific; (3) that oil of chenopodium appears to be a very powerful anthelmintic, though further observations are still necessary to establish this point; and (4) that the best result is to be obtained by making use of both thymol and oil of chenopodium at a suitable interval; the problem of total eradication of ankylostomiasis is, however, not one to be solved by drugs only.

Vomiting sickness caused 134 deaths during the year, as against 196 in the previous year. The investigations by Dr. Scott in support of his theory that vomiting sickness is due to a poison contained in the fruit of ackees (*Bilighia sapida*) were continued. It so happened that while these investigations were being carried out there occurred a definite case of ackee poisoning, and Dr. Scott carried out a post-mortem examination, which revealed changes practically identical with those observed in the animals experimented upon. This case, which was not described as one of vomiting sickness, showed typically the onset, course, and pathological changes of that disease.

As a result of heavy rains malarial fever was prevalent throughout the island, and there was a great increase

among the peasantry and labouring classes; the number of cases admitted to the various hospitals (other than in Kingston) for malaria was 7138. The total number of patients treated in public general hospitals and asylums during the year was 29,537, and the number of outpatients treated was 67,882. There were 516 deaths in hospitals.

## GOOD MILK.

WE noticed in THE LANCET of Nov. 25th, 1916, p. 926, a small pamphlet on practical cow-keeping, written by the Hon. Mrs. Lionel Guest and published under the auspices of the Central Committee for National Patriotic Organisations. The complete book from which the pamphlet was compiled (*The Cow and Milk Book*, John Lane, pp. 175, price 1s. net) is now before us, and is a thoroughly useful little guide dealing with the cow in health and disease, the handling of milk, and the making of butter and cheese. Due stress is laid on the necessity of cleanliness, as well as of knowledge and common-sense, if this branch of farming is to be made profitable. Women, Mrs. Guest thinks, are particularly suitable for looking after live-stock, as farm animals respond to kind and sympathetic treatment. The book may well be commended to all who are keeping cows, or contemplate doing so.

## THE ABBÉ HUC ON PEDICULOSIS.

To the Editor of THE LANCET.

SIR.—Everybody at the present time is interested in lice, and I think the following means of keeping them off may be worth consideration. It is given by the Abbé Huc in his volume of "Travels in Tartary and Thibet," and is probably effective, though perhaps not as elegant a preparation as might now be devised.

Hunger and thirst, fierce winds and piercing cold, wild beasts, robbers, avalanches, menaced death, and actual discomfort—all had been as nothing compared with the incessant misery occasioned by these dreadful vermin. .... We bought a few rapeks' worth of mercury and made with it a prompt and specific remedy against the lice. You take half an ounce of mercury, which you mix with old tea-leaves previously reduced to paste by mastication. To render this softer you generally add saliva; water would not have the same effect. You must afterwards bruise and stir it awhile, so that the mercury may be divided into little balls as fine as dust. You infuse this composition into a string of cotton loosely twisted, which you hang round the neck. The lice are sure to bite at the bait, and they thereupon as surely swell, become red, and die forthwith. In China and Tartary you have to renew this sanitary necklace once a month, otherwise in these dirty countries you cannot possibly keep clear of these vermin.

I am, Sir, yours faithfully,  
Matlock, Jan. 22nd, 1917.

S. SHORE NIGHTINGALE.

## THE COMPLETE DIGESTION OF WAR BREAD.

Dr. William Bramwell (Liverpool) writes to us regarding a patient who is convinced, by an examination of his faeces, that he is passing undigested particles of so-called offal contained in the war bread. The patient, he says, while not in a position to say whether such particles in passing through the alimentary canal have given up all or any part of their nutrient before expulsion as waste, believes that his experience raises a question of vital importance with regard to the use of the R-bread. We have not overlooked the matter, and our correspondent will find an interesting reference to the subject in an annotation on whole-meal bread in THE LANCET of Dec. 2nd, 1916 (p. 949). Probably much less objection would be raised to the so-called offal (itself an objectionable term) if it were finely ground, as we think is likely to be the case in the modern milling processes. Whether fine milling is officially prescribed has not been publicly stated.

*Esculapius* would like to learn from medical men having experience of it whether the prophylactic use of vaccine against winter colds has been found efficacious and lasting. He would like to know whether the vaccines lose their effect after a time.

THE address of the London Insurance Committee is now Insurance-street, W.C. The street is in the Borough of Finsbury, and was originally named William-street, but this was altered a few months ago.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

The following journals, magazines, &c., have been received:—  
Interstate Medical Journal, British Journal of Surgery, British Journal of Dental Science, Review of Neurology and Psychiatry, Annales de Gynécologie et d'Obstétrique, American Medicine, Journal of the Royal Naval Medical Service, Clinical Medicine, American Journal of Surgery, Journal of Missouri State Medical Association, American Journal of Obstetrics, Journal of State Medicine, American Journal of Roentgenology, Mexican Review, &c.

## Medical Diary for the ensuing Week.

### SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Sir Ronald Ross, K.O.B., and Miss H. P. Hudson: An Application of the Theory of Probabilities to the Study of *a priori* Pathometry. Part II.—Dr. J. Brownlee: An Investigation into the Periodicity of Measles Epidemics in London from 1703 to the Present Day by the Method of the Periodogram (communicated by Dr. W. M. Fletcher).—Capt. J. Hammond: On the Causes Responsible for the Developmental Progress of the Mammary Glands in the Rabbit during the Latter Part of Pregnancy (communicated by Mr. J. Barcroft).—Mr. F. H. A. Marshall and Mr. H. T. Halnan: On the Post-ovarous Changes occurring in the Generative Organs and Mammary Glands of the Non-pregnant Dog (communicated by Mr. J. Barcroft).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

#### MEETINGS OF SECTIONS.

Friday, Feb. 2nd.

LARYNGOLOGY (Hon. Secretaries—Cecil I. Graham, Frank A. Rose): at 4 P.M.

Cases:

Dr. E. W. Scripture: (1) A Case of Speech without the Use of the Larynx; (2) Apparatus for the Graphic Record of Speech.  
Sir St Clair Thomson: (1) Three Cases after Laryngo-fissure of Carcinoma Laryngis; (2) Sections demonstrating Very Early Diagnosis of Carcinoma Laryngis; (3) (With Mr. Wilfred Trotter): A Case of Extrinsic Carcinoma Laryngis, Two Years after Operation; (4) Two Cases of Malignant Disease of Nasal Accessory Sinuses after Lateral Rhinotomy (Moure's operation).  
Mr. Cecil Graham: A Case of Malignant Disease of Nasal Accessory Sinuses after Lateral Rhinotomy (a modification of Moure's operation).  
Dr. Irwin Moore: (1) A Case of Carcinoma of Maxillary Sinus after Lateral Rhinotomy; (2) A Case of Choanal (Sphenoidal) Polypus in a Patient aged 6 years; (1) The Original Laryngeal Mirror used by Manuel Garcia.

Mr. Norman Patterson: A Case of Epithelioma of Naso-pharynx after Operation.

Dr. Jobson Horne: A Case of Choanal Polypus.

N.B.—Members of the Section of Surgery are specially invited to attend.

ANESTHETICS (Hon. Secretaries—F. H. Shipway, Ashley S. Daly): at 8.30 P.M.

Paper:

Capt. Geoffrey Marshall, R.A.M.C. (S.R.): Anesthetics at a Casualty Clearing Station.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

MONDAY.—4.30 P.M., Cantor Lecture:—Prof. A. B. Pite: Town Planning and Civic Architecture. (Lecture I.)

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.

FRIDAY.—8.30 P.M., Pathological Evening.

**LECTURES, ADDRESSES, DEMONSTRATIONS, &c.**  
POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY.—4 P.M., Lecture III.:—Dr. C. J. Macalister: The Prevention and Arrest of Venereal Disease in Men. General Sir H. L. Smith-Dorrien, G.C.B., G.C.M.G., D.S.O., Dr. F. N. K. Menzies, Dr. O. May, and Major A. Corbett-Smith, R.F.A., have promised to take part in the discussion.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Prof. C. S. Sherrington: The Old Brain and the New Brain, and their Meaning. (Lecture III.)

THURSDAY.—3 P.M., Prof. F. G. Donnan: The Mechanism of Chemical Change. (Lecture I.)

### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C.

### MANAGER'S NOTICES.

#### VOLUMES AND CASES.

VOLUMES for the second half of the year 1916 will be ready shortly. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half-year's numbers (inland edition) are now ready. Cloth, gilt lettered, price 2s., by post 2s. 4d. To be obtained on application to the Manager, accompanied by remittance.

#### ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

#### TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

#### TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

#### NEWSPAPERS FOR NEUTRAL COUNTRIES.

Newspapers are not at present being sent forward to neutral European countries unless posted direct from the office of publishers or newsagents who have obtained permission from the War Office for this purpose. The Publisher of THE LANCET has obtained the required permission, and he will forward copies direct from the Office to any neutral country on receipt of instructions.

#### Communications, Letters, &c., have been received from

Hunterian Lecture

ON

THE BLADDER IN GUNSHOT AND OTHER INJURIES OF THE SPINAL CORD.

Delivered at the Hunterian Society,

BY J. W. THOMSON WALKER, M.B. EDIN.,

F.R.C.S. ENG.,

SURGEON TO THE KING GEORGE HOSPITAL; CONSULTING UROLOGIST TO THE STAR AND GARTER HOSPITAL; ASSISTANT SURGEON TO ST. PETER'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN.—My first words must be those of thanks to the Council of the Hunterian Society for the invitation to address you. I had no doubt as to my strong desire to accept the invitation, but I had very grave doubts as to whether, in the present time of great stress, when there is so little opportunity for quiet consideration and accurate writing, I was justified in undertaking so important a task.

Had this been a time of peace, my inclination in addressing a society, the patron-saint of which is John Hunter, would have been to select a subject in which surgical pathology has some considerable part. But this is war-time, and I see in the subject I have chosen an opportunity of bringing before you some war-work which I hope may have a certain practical value, since it is based upon personal observation of a class of cases never before collected together in such great numbers.

At the Star and Garter Hospital (65 beds) there have been altogether 111 cases, and with the exception of a very few these have been cases of spinal injury. In conjunction with my colleague, Sir David Ferrier, I have been responsible for the observation and treatment of the complications affecting the urinary organs in these cases. At the King George Hospital there have been since May, 1915, 339 cases of spinal injury in the wards of my medical and surgical colleagues on the staff and in the wards under my care at that hospital.

To all of these cases I have had free access, and I seize this opportunity of offering my grateful thanks to Lieutenant-Colonel R. J. C. Cottell, R.A.M.C., officer commanding, and to Lieutenant-Colonel Donald Armour, R.A.M.C. (T.), Major Newton Pitt, R.A.M.C. (T.), Captain Sir John Broadbent, Bart., R.A.M.C. (T.), Captain Farquhar Buzzard, R.A.M.C. (T.), Captain James Collier, R.A.M.C. (T.), and Dr. Raymond Crawford for the opportunities they have afforded me of studying the cases under their care. I would also acknowledge my indebtedness to Major H. J. Parry, R.A.M.C., D.S.O., and to Major J. L. Dickie, R.A.M.C., for obtaining statistics of cases at the King George Hospital and the Star and Garter respectively.

I propose to look shortly at the anatomy and physiology of micturition. Next I shall outline the recognised

No. 4875.

variations in micturition brought about by disease and injury of the spinal cord. Then will come consideration of the cases that have come under my observation, and, lastly, some discussion of the subject of treatment.

ANATOMY AND PHYSIOLOGY.

The centre which is credited with the control over the act of micturition lies in the lumbar enlargement of the cord. Nerves pass to the bladder in two groups—a lumbar group and a sacral group. (Figs. 1, 2.) The lumbar nerves issue from the cord in the third, fourth and fifth lumbar nerve-roots and pass through the sympathetic chain, without making connexion with the cells of the sympathetic ganglia, to the inferior mesenteric plexus. From these ganglia two hypogastric nerves pass to the hypogastric plexus. Thence filaments pass to the muscular wall of the bladder. The second group consists of two nerves derived from the second and third sacral nerves, and named the *nervi erigentes*. These two nerves pass straight to the hypogastric plexus, from which the fibres are distributed to the bladder. Ganglion cells are also found in the course of the nerve filaments in the muscular wall of the bladder. To these nerves may be added the pudic nerve (second, third, and fourth sacral) which supplies the compressor urethrae muscle, or external sphincter, and the perineal muscles. Recent investigators conclude that a cortical centre for the bladder is situated in the motor area, at the spot where the arm and leg centres join.

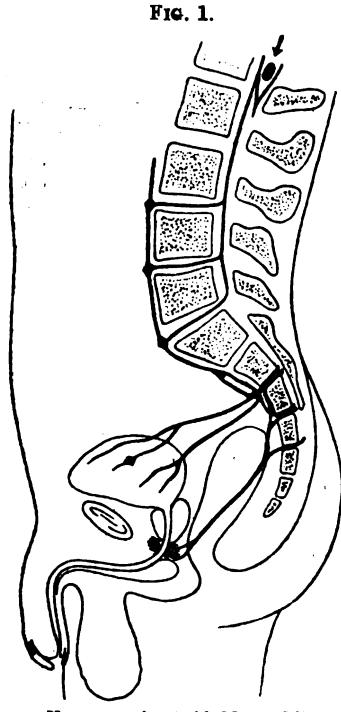

While the above is the generally accepted view, the work of Gaskell<sup>1</sup> shows that the centre for micturition lies outside the spinal cord, in the hypogastric and mesenteric plexuses of the sympathetic. Müller,<sup>2</sup> applying Gaskell's view,

states that after complete separation of the bladder from the cord reflex micturition still takes place. A final decision in this matter does not appear to have been arrived at. Bechterew, in commenting on this relegation of the micturition centre to a lower level, states that though it may be shown in animals, the spinal bladder centre is so highly developed in the human being that its destruction under any conditions is followed by an abolition of bladder contraction. Justschek<sup>3</sup> has shown in animals that the

bladder can contract spontaneously in virtue of the ganglia in its muscular wall.

*The Act of Micturition.*

The urine is retained in the bladder partly by mechanical conditions and partly by tonic contraction of the vesical sphincter. In the cadaver urine does not escape from the bladder when in the recumbent or the erect posture, and some amount of force is required to separate the elastic walls of the urethra at the vesical orifice. The male bladder is provided with a double sphincter, a non-striped or true sphincter, and a striped or external sphincter (compressor urethrae muscle). The non-striped sphincter has a constant involuntary action, but it is stated that some amount of voluntary control may be exerted over it.

Nerves passing to bladder and its sphincters.

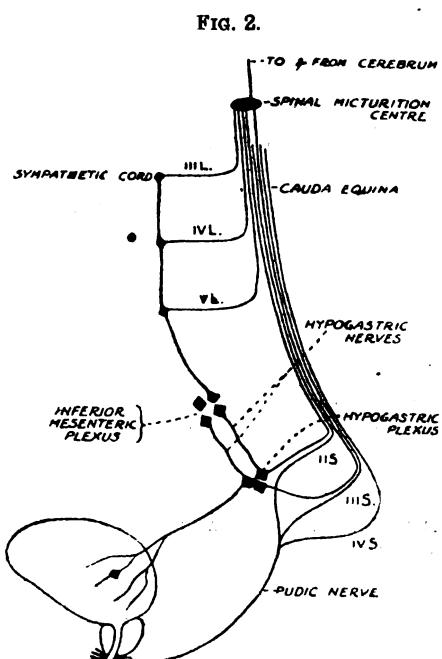

Diagram of nerves of bladder, explanatory of Fig. 1. III.L, IV.L, V.L, Lumbar nerve roots; I.I.S, II.I.S, III.I.S, IV.S, Sacral nerve roots.

Under ordinary conditions the urine is retained in the bladder by the tonic contraction of the true, or non-striped, sphincter. When, however, the pressure within the bladder becomes too great, and it is still desired to retain the urine, the true sphincter is reinforced by voluntary contraction of the external sphincter. Under certain circumstances the action of the true sphincter may be entirely abolished and the external sphincter will take its place. I pointed out<sup>5</sup> in 1905 that after the operation of suprapubic prostatectomy, in which the prostate and prostatic urethra are removed, the internal sphincter is inactive in the majority of cases, and the sphincter function is taken over by the striped compressor urethrae muscle.

Micturition takes place in response to impulses which pass along the reflex arc. Impulses originating in the bladder pass by the afferent nerves to the micturition centre, and from this two sets of impulses issue by way of the efferent nerves. One set exerts an inhibitory influence on the true sphincter and causes it to relax, and a second set of impulses pass to the muscular wall of the bladder (detrusor) and stimulate it to contract. The manner in which this reflex is initiated has given rise to some discussion. Two sensations are concerned: 1. As the bladder becomes filled with urine the tension of the fluid gradually increases, and the pressure exerted on the bladder wall causes increasing waves of contraction of the bladder muscle. 2. When the bladder is distended contractions of the wall become sufficiently strong to force a few drops into the sensitive prostatic urethra, from which impulses pass to the spinal centre, giving rise to efferent inhibitory impulses to the sphincter and motor impulses to the detrusor. In normal micturition both these factors probably have a place. Either may, however, alone produce the reflex act. The prostatic urethra is removed in the operation of suprapubic prostatectomy, and after the operation micturition is normally performed.<sup>6</sup>

*Cerebral control of micturition.*—The influence of the cerebral cortex on micturition is exerted in two ways. 1. A voluntary inhibition of the reflex of micturition becomes established in the child about the second year. Periodic reflex micturition, the natural state in the infant, no longer takes place, but the urine is retained until a convenient opportunity occurs, when the bladder is emptied voluntarily. When the bladder becomes distended so that the desire to micturate is strongly felt, the control becomes voluntary, and is exercised by contraction of the compressor urethrae or external sphincter, and also of the perineal muscles.

2. The voluntary part of the act of micturition consists in relaxation of the sphincter, contraction of the abdominal muscles, and the contraction of the bulbo-cavernosus muscle at the end of the act. Contraction of the abdominal muscles alone will not produce micturition, but increases the flow of urine, once micturition has commenced. Relaxation of the external sphincter is the voluntary part of the initiation of normal micturition in the adult, and this is probably sufficient in itself to induce the escape of urine into the prostatic urethra, and start the reflex act.

#### BLADDER STATES IN SPINAL INJURY AND DISEASE.

Before passing to consider the cases of nerve lesion affecting the bladder that have come under my observation, I will refer shortly to the bladder states that are recognised as the result of animal experiment and observation on cases of injury to, and disease of, the spinal cord.

1. *Retention of urine.*—Paralysis of the detrusor muscle, while the sphincter remains active, causes retention of urine. This condition, if prolonged, leads to retention with overflow. Less complete nerve lesions may produce delay in commencing micturition, a poorly projected stream, and dribbling at the end of micturition.

2. *Retention with overflow (passive incontinence).*—Relaxation of the bladder muscle permits the accumulation of a large quantity of urine (stated at 1½ litres, Bechterew). At length the intravesical tension becomes so great that some urine flows away. The bladder does not, however, empty itself; no reflex micturition takes place, but only the surplus beyond a certain large accumulation escapes. The condition has been looked upon as a passive incontinence, the bladder remaining entirely flaccid. Corner<sup>7</sup> suggests that in the moderately distended paralytic bladder rhythmic contractions continue and expel a few drops of urine every few minutes, but when the distension becomes greater the contractions cease and the overflow consists of drops of urine

mechanically displaced from the bladder by influx from the ureters.

3. *Periodic reflex micturition (active incontinence).*—Here a quantity of urine accumulates in the bladder, and then the reflex act of micturition takes place and the urine is discharged. When the same quantity of urine accumulates again the reflex act is repeated. The reflex micturition cannot be voluntarily controlled either by initiating the act, or by inhibiting it, or stopping it while it is taking place. Here the state is that of the infant's bladder, cerebral control being absent. This condition is developed where there is section of the cord at any part above the lumbar micturition centre.

4. *Paralytic incontinence.*—In this state there is a flaccid bladder and atonic sphincter, and the urine dribbles away from the bladder without accumulating. This is said to develop when the lumbar centres are destroyed, and the bladder is cut off from the cord altogether.

#### OBSERVATIONS ON CASES OF BLADDER LESION IN SPINAL INJURY.

While the large numbers of cases of spinal lesion already referred to have come under my observation, it has been impossible in the time at my disposal to make full notes for the purposes of statistics on all the cases. I have, however, obtained detailed notes on 70 cases, and have to thank my house surgeon, Dr. A. K. Selim, for valuable help in note-taking. The condition of the urinary tract is the most important clinical factor in these cases of spinal injury. Urinary infection may be a contra-indication to operation on the spine, or it may cause death soon after an operation. It may be fatal where operation has already given promising results, or where without operation the case is showing signs of improvement in the nerve lesion. There are many points of great interest and importance in regard to the urinary organs in these cases, but I shall only have time to discuss two of these—namely: (1) Variations in the function of micturition, and (2) infection of the urinary tract.

##### Variations in the Function of Micturition.

Two distinct stages were observed in the cases that have come under my notice: (1) A stage of complete retention; (2) a stage of periodic reflex micturition.

1. *Stage of complete retention.*—There is a stage of complete retention commencing from the time of the injury and lasting for a varying period of time. During this time there is atony of the detrusor muscle, but the sphincter remains active. As a result the bladder is distended with urine. Careful inquiry elicits that the bladder is emptied on an average from a half to two hours before the injury, so that it probably contains a small quantity of urine when the wound is received. The shock of the spinal injury must be very considerable, and it is unlikely that during the first 6 or 8 hours after that much urine is secreted. By the end of from 12 to 24 hours, however, a considerable amount of urine has accumulated. In the great majority of cases the patient is unconscious of the fact that the bladder is distended, but in a proportion of cases the distension is felt and causes acute pain.

After a time, if the retention is not relieved by catheter, urine begins to dribble away, the bladder remaining distended and the overflow escaping (retention with overflow). I have not been able to ascertain whether this escape of urine is a trickle of fluid from the urethra as a result of pressure from the natural resiliency of the bladder wall, or whether active contractions of the bladder take place.

The catheter is passed and the bladder emptied at a varying time after the wound was inflicted. From that time catheterisation is continued at more or less regular intervals. Between the times of catheterisation the bladder becomes distended with urine, but there is no longer any escape.

The duration of this state of complete retention varies in different individuals, the shortest that I have noted being 24 hours and the longest 18 months. The average duration in 30 cases was 55 days. In one case there was said to have been no retention, and periodic reflex micturition commenced immediately after the injury. In all the others of 70 carefully investigated cases, this stage of retention was, or had been, present.

2. *Stage of periodic reflex micturition (active incontinence).*—To the first stage of complete retention there succeeds, after days, weeks, or months, a second stage of periodic reflex

micturition, which, unless improvement in the spinal lesion takes place, is the permanent state of the bladder.

(a) *Transition stage*.—The bladder does not, however, suddenly pass from a condition of retention with overflow, or complete retention, to one of active incontinence in its fully developed form. There is a transition period in which the bladder is still distended, or partly distended, with urine, but active contraction of the bladder wall takes place, and expels a small quantity of urine at intervals. The commencement of this period is marked by the necessity for providing a bottle to receive the urine which is discharged at frequent intervals between the times at which the catheter is passed. Very frequently at this time the catheter is omitted, although it may still be passed once a day or oftener for the purpose of washing the bladder. The bladder, which at first was distended, left to itself gradually becomes more contracted, until the quantity of residual urine left after micturition is very small, or there is none at all. The advent of cystitis hastens the contraction of the bladder and reduces the quantity of residual urine.

(b) *Periodic reflex micturition*.—In the fully developed second stage the bladder is a purely reflex organ. The sphincter is active, and the urine accumulates in the bladder. When the set capacity of the bladder is reached the detrusor muscle contracts, the sphincter relaxes, and the urine is discharged in a powerful stream. This is active incontinence. It is an involuntary act. The patient is unable by any effort of will to initiate the reflex, nor can he inhibit the micturition. In the majority of cases he is unaware that micturition is taking place. The bladder holds from 2 to 10 ounces, and the urine is discharged at intervals of a quarter or half an hour up to two or three hours. Where severe cystitis is present the capacity is much diminished and the bladder holds only one or two ounces. When cystitis is mild or absent the capacity of the bladder is greater. Artificial distension of the bladder beyond its set capacity results in the fluid being discharged alongside the catheter, and the proceeding usually causes pain. Operation on the bladder in cases of severe cystitis in this stage showed the muscular wall thick, and the organ appeared to be in a permanent state of partial contraction. Cystoscopy in a number of cases in this stage showed chronic cystitis, but there was no trabeculation such as is found in the bladder in tabes.

#### *Bladder Sensation.*

The two varieties of sensation connected with the function of normal micturition are the sensation of distension and the urethral sensation which is felt in the prostatic urethra. In the cases of paraplegia under consideration the urethral sensation is more frequently and completely abolished than the tension sensation. The feeling of tension produced by an over-full bladder is preserved in greater or less degree in a fair number of cases. This may be felt for a time and then be abolished, or it may be the first sign of improvement taking place after being completely in abeyance for a prolonged period. The sensation is not so defined as in the normal individual unless recovery is far advanced. It amounts to a vague sensation of fullness somewhere in the abdomen, which in time the patient comes to connect with a distended bladder, the knowledge being checked by the patient feeling the distended bladder with the hand in the abdomen. Urethral sensation is abolished. The patient is unable to feel the urine passing or the catheter being introduced. In some cases, especially cases of cauda equina lesion and cases of partial cord lesion which are recovering, the passage of the catheter can be felt. The prostatic urethra, especially at the entrance into the bladder, is the sensitive part, the anterior urethra remaining anaesthetic.

#### *Variation in the Bladder Condition in Lesions at Different Levels.*

In the cases that have come under my observation there are examples of injury in all the regions of the cord.

In the cervical and dorsal region of the spine voluntary micturition was present in a few cases where the injury was slight. In all the other dorsal and cervical cases there was complete retention of urine when the injury was recent, and periodic reflex micturition when the date of the injury was more remote. The cases of periodic reflex micturition included those which I have described as in the transition stage—namely, periodic reflex micturition with incomplete

emptying of the bladder, and also those where the final stage of periodic reflex micturition had been reached by the bladder having regained the power of completely emptying itself. All the above cases represent lesions situated above the lumbar centre for micturition.

It is of interest to examine those cases where the upper part of the lumbar spine was involved in the injury, for at this level lies the micturition centre. There were three cases of injury involving the eleventh and twelfth dorsal and first lumbar vertebrae; one affecting the first lumbar, one the second lumbar. In two of these cases the nerve symptoms pointed to a partial lesion of the cord. In one of these voluntary micturition was performed, and in one of them there was periodic reflex micturition. In three of the cases the symptoms pointed to a complete lesion, and in each of these was periodic reflex micturition. In none of the cases was there any resemblance to the condition which has been described as following destruction of the lumbar centre in experimental work on animals—namely, paralytic incontinence, the urine dribbling away from a flaccid empty bladder through a flaccid sphincter. In one of these cases the lesion was verified by operation by Lieutenant-Colonel Armour, the cord being found "badly pulped" at the level of the twelfth dorsal and first and second lumbar vertebrae.

Lesions of the cauda equina were present in 14 cases examined. The effect of the nerve injury on the act of micturition showed remarkable variation. Three cases of partial lesion of the cauda equina passed urine voluntarily and normally. Eight cases of partial lesion had periodic reflex micturition, following a stage of complete retention. Two cases of partial lesion of the cauda equina had complete retention. One of these was in the early stage, two months only having elapsed since the injury. A second, a unilateral lesion, had complete retention for 18 months. One case had a complete lesion with retention.

Complete retention after the injury, followed by periodic reflex micturition at a later date, was the rule in these cases, as in those where the injury involves the cord. A feature of the cauda equina cases was variation, from time to time, in the functional state of the bladder. In three of the cases there were recurrent attacks of retention of urine lasting from a week to a month after reflex micturition had become established.

Periodic reflex micturition or active incontinence is generally accepted as the condition which results when the micturition centre in the cord is cut off from the control of the brain, such as occurs in supralumbar lesions. For its development the reflex arc, together with the spinal centre, is supposed to be intact. It is not conceivable in this theory that injury to the afferent or efferent nerves of the bladder, within or without the spinal canal, could bring about this state of micturition. Yet periodic reflex micturition has developed in these 8 cases of cauda equina lesion.

These cases of injury to the lumbar enlargement of the cord and to the cauda equina support the view of Gaskell, already referred to, that the centre for micturition does not lie in the spinal cord but in the hypogastric and mesenteric plexuses. Possibly they may give to the ganglion cells in the bladder wall a more important rôle than has been hitherto ascribed to them.

The most striking points in considering the variation in the effect of injuries at different levels on the act of micturition may be summarised. Complete retention occurs, at the commencement, in all cases where micturition is affected, at whatever level the injury may be, and it occurs in cauda equina lesions as well as in cord lesions. Periodic reflex micturition is the second phase in all lesions of the cord, not excepting those of the lumbar enlargement. Periodic reflex micturition develops in more than half the cases of cauda equina lesion, but occasionally voluntary micturition follows directly on a period of complete retention.

#### *Urinary Infection.*

The most common and most fatal complication in a paralysed bladder is infection. Over 90 per cent. of cases of spinal injury arriving at the Star and Garter Hospital have a serious infection of the urinary tract, and all cases have at some period passed through a stage of severe infection. Of the total 111 patients 19 have died, all from urinary infection. At the King George Hospital 339 cases of spinal injury have been admitted, 22 were transferred and 160 have died, practically all from urinary infection.

It is important to inquire how the infection occurs and what is its nature. In all cases the infection takes place at an early period after the injury, usually within the first week. The circumstances surrounding the first few days following the injury render these cases peculiarly liable to the invasion of bacteria. The patient lies exposed for some hours, and in many cases has been inaccessible for two or even more days. During this time the urine collects and the bladder is greatly distended. In this state the patient, still suffering from profound shock, arrives at the casualty clearing station, where a catheter is passed and the bladder is emptied. The rush of urgent and serious cases, the very great difficulties in pursuing a perfectly aseptic technique, the ready soil which an over-distended paralysed bladder presents to the invasion of bacteria, together render infection extremely probable. And should it not take place here there are ample opportunities during transport to a base hospital either in France or in England for the bladder to become infected.

The cystitis which results is of a particularly severe character, and in most cases it is of the haemorrhagic type. Cystitis in itself is not, or only very rarely, a fatal disease, and should the infection remain confined to the bladder no serious harm would result. In a large proportion of cases, however, the infection ascends to the renal pelvis, causing pyelitis, and invades the renal substance, when septic pyelonephritis results.

Septic pyelonephritis is a peculiarly fatal disease, and is the cause of death in the great majority of fatal cases of gunshot wound of the spine that survive the initial shock. The onset of pyelonephritis is marked by a rigor followed by a sudden rise of temperature to 102° F. or higher. There is pain in the loins, more marked on one side, and the kidney is tender and may be enlarged. The abdomen is distended with flatus and is rigid on the side of the inflamed kidney. The second kidney is not tender or enlarged. The urine is slightly diminished in quantity, but is not suppressed. It retains the characters of the urine in alkaline cystitis which were present before the onset of the renal complication. Haematuria, which is sometimes severe and may be continuous, frequently appears with the onset of the fever. Herpes of the lips is often present. The temperature may remain high or may have a swinging type, with repeated rigors. After a week the symptoms may subside or they may persist, the temperature remaining high. The patient becomes more drowsy, vomiting and hiccup appear, muttering delirium supervenes, and the patient passes into coma and dies.

A more common type seen at a base hospital is chronic septic pyelonephritis, with recurring attacks of acute pyelonephritis. The patient has passed, at the commencement of the kidney infection, through a severe attack similar to that described. The temperature settles down to normal and the symptoms have disappeared. At intervals of some weeks or months, but often of only a fortnight, there are attacks of acute pyelonephritis. The temperature rises suddenly to 102° or 103°. It remains up for five or seven days and then returns to normal again, and remains normal or subnormal until the next attack. (Fig. 3.)

After a time the condition becomes one of chronic urinary septicæmia. The patient has a sallow, earthy complexion; the skin is dry and harsh, and seldom sweats. The lips are dry and the tongue becomes glazed, dry, and cracked. There is loss of appetite, a buccal dysphagia results from the dryness of the mouth, and only fluids are taken. The bowels are constipated. Progressive loss of flesh, apathy, and drowsiness become more and more marked. Polyuria amounting to 80 or 100 ounces in 24 hours, may be observed in the intervals between attacks, while the quantity of urine is diminished during an acute attack. The temperature is subnormal.

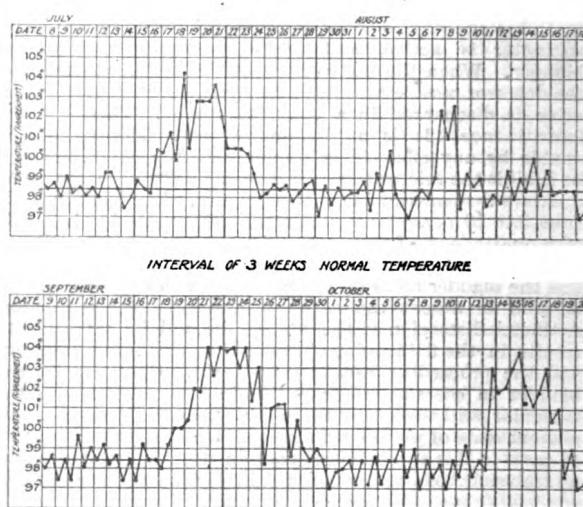

The course of chronic urinary septicæmia is interrupted by acute attacks of varying severity, frequently following some exciting cause, such as exposure to cold or too vigorous bladder washing. Finally the patient dies during an acute attack.

It is frequently a matter of difficulty to distinguish the septic state, due to absorption from a sloughing bedsore, from the symptoms of acute septic pyelonephritis. With a painful, enlarged, tender kidney, protected by rigid abdominal muscles, there is no difficulty in the diagnosis. But the pain may be slight or misplaced. It is not infrequently absent, or only elicited on careful questioning. In some cases of

paraplegia the pain is felt not in the kidney area but in the epigastrum, and the position is misleading. Rigidity of the abdominal wall is a feature of a number of cases of paraplegia, quite apart from any renal infection. This may mask a tender kidney, or it may lead to an erroneous value being placed on the muscular rigidity. The enlargement of the kidney may be slight and difficult to detect. The urine forms no guide. It is an alkaline ammoniacal, occasionally blood-stained urine of alkaline cystitis.

In such difficult cases the points on which I place most reliance are tenderness of the kidney and the character of the temperature. Tenderness is almost always present in some degree, and a comparison of the two sides will help. The chief characteristic of the temperature chart is the occurrence of isolated attacks of high temperature lasting a week or ten days, with intervals of varying length, during which the temperature is normal, or, in advanced cases, subnormal. (Fig. 3.) The raised temperature due to absorption

FIG. 3.

Temperature chart of case of chronic pyelo-nephritis with acute exacerbations.

from a septic bedsore shows an irregular daily rise, continued over some weeks, with gradual improvement and without any definite periods of normal and subnormal temperature, or any well-defined short attacks.

In the late stages when both kidneys are infected the distinctive features are the red, glazed, dry tongue, headache, thirst, inability to take solid food, rapid emaciation, and dry, harsh skin. Vomiting is a late and serious symptom.

In investigating a case of paraplegia with fever it should not be forgotten that, owing to the anaesthesia, a large abscess may form in the neighbourhood of a bedsore or elsewhere and be quite painless, so that the patient does not draw attention to the spot.

#### TREATMENT.

Treatment of the urinary tract in paraplegia resolves itself into two chief lines: (1) Provision for the removal of urine; (2) treatment of septic complications.

#### *The Removal of Urine.*

Cases of paraplegia are divided into two classes in regard to the disposal of the urine. In the early stages there is complete retention and the urine must be removed artificially; in the later stage there is active incontinence, and the only necessity is to collect the urine as it is passed. In the stage of retention, some means of emptying the bladder must be used. Three methods are available. A catheter may be passed at regular intervals, a catheter may be tied in the urethra (catheter à demeure) or the bladder may be drained by operation.

1. *Catheter life.*—The passage of a catheter is the method that has been universally adopted. A catheter is passed at the earliest moment after the injury, and at regular intervals,

usually three times in 24 hours after this until active incontinence is established. Under favourable conditions the first catheterisation may be performed seven hours after the receipt of the injury. The average time that elapsed before a catheter was passed in 46 cases was 27 hours. Two patients lay out for four days, and four for three days before they could be reached. The average period during which the use of the catheter, for the purpose of emptying the bladder, is necessary is two months. In one case the duration of the retention stage was 18 months, in another 15 months, but these cases are exceptional.

2. *The tied-in catheter: catheter "à demeure."*—The tied-in catheter has been resorted to in a number of cases. In some for the purpose of draining an infected bladder, in others in order to avoid the necessity of catheterisation three or more times in 24 hours. The constant presence of the catheter in the urethra very quickly sets up urethritis, with purulent discharge and swelling of the urethral mucous membrane; and after a few days the method has to be abandoned in most cases. This method, useful for a short time in an emergency, is quite unsuitable for the continued treatment of retention in paraplegia. The danger which attends it is the development of a perineal abscess and the formation of a urinary fistula, or the sloughing of a large portion of the urethral wall, with the overlying skin. The tying-in of a metal catheter will bring this about in a few days, and is an extremely dangerous procedure, even in cases where no nerve lesion exists.

3. The third method is drainage of the bladder through a suprapubic wound. I shall discuss this method later.

#### *Treatment of the Septic Complication.*

1. *Local treatment by bladder washing*—It is unnecessary to describe this in any detail, but one or two observations may be made. The best method is to use an irrigator, the reservoir holding 3 or 4 pints, and being raised about 3 feet above the level of the patient. By means of rubber tubing and a glass nozzle which fits the catheter, 3 ounces of fluid are run into the bladder and allowed to run out again into a vessel between the thighs, and this is repeated until the contents of the reservoir are exhausted. As large a catheter as will pass along the urethra should be used. No attempt should be made to distend the bladder beyond the amount of fluid it holds readily. If the pressure is raised too high by over-distending the bladder there is danger of forcing septic material up the ureter and causing an ascending infection or a recurrence of pyelonephritis when this has already been established.

Strong antiseptics should be avoided in washing the bladder. They cause swelling of the mucous membrane and an increase in the cystitis. The action in bladder lavage is as much a mechanical as a chemical one, and the total quantity of fluid used is of as much importance as the character of the antiseptic employed. Before commencing bladder washing the reaction of the urine should be tested, and a wash selected which will counteract extreme acidity or extreme alkalinity, if either state exist. In selecting a bladder-wash, therefore, and also as I shall presently state, in choosing drugs for internal administration, the reaction of the urine should be the first guide.

Another point in regard to the reaction of the urine in bladder washing is that deposits in the bladder wall take place: mucus shreds and flakes in an acid cystitis, and phosphatic material and mucoi in an alkaline cystitis. An attempt should be made at the beginning of each washing to remove these deposits by the use of a wash of different reaction. An acid wash will dissolve phosphatic débris, and an alkaline will facilitate the washing away of thickropy mucus in an acid cystitis. A large number of different bladder washes have been tried, but no one is a specific, and the fluids commonly used are found to be as good as any.

In alkaline cystitis, and this forms the great majority of cases of cystitis in paraplegia, boric acid solution one half the saturation strength may be used. If the urine be powerfully alkaline, and especially if fragments of phosphatic material are being formed and passed, a preliminary wash with a solution of acetic acid (B.P.), one drachm to the pint, should be used, and followed by boric solution, or large quantities of the acetic acid solution may be used for several days at a time. At the same time steps should be taken to render the urine acid by means of drugs given by the mouth.

In an acid cystitis normal saline solution, in full or in half-strength, is frequently very successful. Permanganate of potash solution (1 in 8000), peroxide of hydrogen solution (1 in 20 of 10 volume), and silver nitrate solution (1 in 10,000) are all useful. A note may be made in regard to the newly introduced chlorine preparations. The solutions are intensely irritating to the bladder, and should be used with caution. A solution of 1 in 20,000 is sufficiently strong to use at first, and this may cautiously be increased in strength.

2. *Medicinal treatment.*—In giving medicines the two objects kept in view are the reduction of extreme acidity or extreme alkalinity of the urine, thus reducing the irritation of the bladder and, secondly, the administration of urinary antiseptics.

An acid urine is easily reduced to alkalinity by giving drugs such as bicarbonate of soda, potassium citrate and acetate, and diuretic waters such as those of Contrexéville, Vittel, and Vichy. An alkaline urine is usually difficult to render acid. The two drugs that have a powerful acidifying action on the urine are sodium acid phosphate (introduced for this purpose by Dr. Robert Hutchison), and sodium or ammonium benzoate. Sodium acid phosphate should be given alone and the dose increased every few days till the urine gives an acid reaction. The limit of tolerance is reached by diarrhoea being produced. Four or eight drachms in 24 hours are usual doses. The benzoates should be given in doses of 10 to 20 grains three times daily.

It is impossible here to enter into the details of treatment by urinary antiseptics. This has been discussed fully elsewhere.<sup>8</sup> It is sufficient to repeat that hexamine (urotropine) depends for its antiseptic action on splitting and giving off formaldehyde, and that this takes place only in an acid medium. Boric acid is the best urinary anti-septic when the urine is alkaline. It may be combined with ammonium benzoate, and when the urine has become acid hexamine may be added. When the urine is acid hexamine may be given alone.

In the early stage of an acute cystitis, the first object should be to soothe the intensely inflamed mucous membrane by drugs and diuretic waters, occasionally with the administration of sandal-wood oil.

3. *Vaccine treatment.*—Vaccine treatment has proved of great value in treating the chronic cystitis of these paraplegic cases. Vaccine therapy forms a chapter in itself, and there is not time to do more than to recommend its use.

#### DRAINAGE OF THE BLADDER BY SUPRAPUBIC CYSTOTOMY.

Lastly, I come to the subject of cystotomy, which I have deferred in order that I may link up the question of drainage in the different stages. In the first place, I wish to discuss suprapubic cystotomy as a prophylactic measure.

It should not too readily be accepted that infection of the bladder, with resultant ascending pyelonephritis, is inevitable. The infection is not a haemogenous infection from the bowel or elsewhere; it is an ascending infection introduced by the catheter. I have already referred to the circumstances in which catheterisation of these cases is commenced and to the very great difficulties of a perfect technique under such conditions. But the real danger, the fatal complication, is not the cystitis itself; it is the ascending pyelonephritis (surgical kidney) that results from it.

#### *Cause of the Ascending Infection.*

It is worth while inquiring how this ascending infection comes about. There are natural barriers to the ascent of infection. The lower end of the ureter penetrates the wall of the bladder very obliquely, and its longitudinal layer of muscle passes into the trigone. When the bladder is distended the trigone is pushed down and the bladder wall stretched, so that the intramural portion of the ureter becomes more oblique and flattened, and the intravascular tension further closes the lumen by pressure. When the bladder is contracted the intramural portion becomes shortened and less oblique, but the mucous membrane is thrown into folds which prevent a reflux of fluid. The downward flow of urine is a further protection against the ascent of bacteria. When the bladder is forcibly over-distended by injecting fluid through a catheter these barriers are overcome, and fluid may be forced up the ureter.

In the early retention stage of these paraplegic cases the bladder is greatly over-distended, sometimes for several

days; and there is no doubt that the barriers to a reflux into the ureter must be considerably weakened if not entirely overcome. Further, the effect of the over-distension and consequent great increase in tension have caused damage to the kidney. Guyon and Albaran<sup>9</sup> made experiments in 1897 on the effect of acute retention of urine on the kidneys. They found that an aseptic pyelonephritis resulted. There was acute congestion which might go on to intratubular hemorrhages, with desquamation of epithelium of the tubules. Clinically, there was lessened secretion of urine, while the urine contained a reduced quantity of salts, and there were present blood, renal cells, blood casts, and epithelial casts. Relief of the retention was followed by polyuria and the symptoms subsided if no sepsis were present.

In these paraplegic cases we have the barriers against ascending infection overcome and the kidney damaged, and therefore unusually susceptible to the invasion of bacteria. The smallest slip in technique will surely lead to cystitis and ascending pyelonephritis, and such a slip must be guarded against, not only at the first catheterisation, but during the whole retention stage of many weeks, or even months. Over-zealous washing of an inflamed bladder with too strong antiseptics or too great distension of the bladder will just as readily produce an ascending infection as a septic catheterisation of the original over-distended bladder. The ascent of infection from the bladder to the kidneys is, in my view, due to pressure or intravesical tension. There are other factors that may play some part. The motile bacillus travels upwards, even against stream. The fact that there is a nerve lesion may reduce the resistance to bacterial invasion. Probably the ureteric orifice is more easily forced in such cases. But these are all of secondary importance, and the raised intravesical tension caused by chronic retention is the deciding factor.

#### *Prophylactic Cystotomy.*

Is there a remedy? Certainly there is, and it lies in early and continuous drainage of the bladder. Continuous urethral drainage by catheter is unsuitable, as I have already pointed out. The only method that is efficient is suprapubic cystotomy. Let me make the position quite clear. Suprapubic cystotomy here advocated is not suprapubic cystotomy for the drainage of an already infected bladder. I see a fair number of these cases and will discuss them later. The suprapubic cystotomy suggested is to take the place of the catheter entirely. No catheter is passed at any time. One catheterisation may be sufficient to cause the whole damage—cystitis and ascending pyelonephritis. It is suggested that the bladder be opened suprapublically at the earliest possible moment, before any catheter has been introduced, and be drained continuously until the second stage of active incontinence is reached; as shown by the patient passing urine along the urethra, as well as draining by the suprapubic tube. I have seen no cases in which this has been done, and have not heard of its having been carried out.

Will this prevent cystitis? It may in some cases, but I do not expect it will in all; but I hope that the cystitis when it occurs will be of a milder type. Cystitis in an open bladder is a very different affair from cystitis in a closed, paralysed bladder. There are very few cases of cystitis in an open bladder that cannot be cleared up by the use of continuous irrigation. The important point is that there is no urinary tension inside a drained bladder, and therefore no tendency to ascending infection; and this is the object of the drainage.

If 20 cases were treated thus and followed up carefully the result could easily be ascertained. I do not doubt that the results would be much better than those in 20 consecutive cases treated by catheter or by bladder drainage after the bladder had been infected by the catheter. Are all cases to be placed in the same category? I have already stated that the same initial stage of retention may result from a lesion of any part of the cord or the cauda equina and, later, be followed by active incontinence or voluntary micturition. All cases are thus equally in danger. It is not the extent of the nerve lesion that matters: it is the paralysis and over-distension of the bladder.

Is it practicable? This is a question that cannot be fully answered by a surgeon working at a base hospital. The great majority of cases are catheterised for the first time at a casualty clearing station. What the facilities are at this

station for the performance of a rapid suprapubic cystotomy only those on the spot can say. A more practical point for me to discuss is: What time may be allowed to elapse before draining the bladder in these cases, so that the patient may be conveyed to some place where suprapubic cystotomy can be safely performed without being subjected to undue risk by delay in emptying the bladder?

It is obvious that the sooner the drainage is done the better, but I do not think great harm would result if the bladder could be drained in 24 or even 48 hours after the receipt of the injury so long as no catheter was passed before that. Morphia might, in the absence of other contraindication, be given if necessary. The operation is not a difficult or a long one. The anaesthesia in most cases extends above the suprapubic area, so that no general anaesthetic is necessary. The bladder is fully distended with urine, so that no catheter need be passed.

A vertical incision  $\frac{1}{2}$  inches long is made from the upper border of the symphysis pubis in the middle line, the rectus sheath and pyramidalis muscles cut through, the fibres of the recti separated, and the forefinger seeks the upper margin of the symphysis pubis, detaches the thin transversalis fascia from this, and sweeps the peritoneum upwards. The firm cushion of the bladder wall can then be felt. A scalpel is passed along the finger and plunged through, and the finger slips into the bladder cavity as the urine rushes out.

A self-retaining Pezzer rubber catheter on a stilette is pushed along the finger, guided into the bladder, and the finger removed. A small wick of gauze is placed in the prevesical space, and one, or at most two, silkworm-gut stitches bring the rectus sheath and skin together above the tube. A broad layer of gauze is thoroughly covered with boric acid crystals (not powder) and another layer of gauze over this, so that the crystals are sandwiched in the gauze, and this applied round the catheter, and held in place by two strips of adhesive plaster. The end of the catheter is carried into a bottle between the thighs, or at the side of the loin, an additional piece of rubber tubing being added to the catheter, if necessary. This arrangement will suffice to drain the bladder until a base hospital is reached and some more elaborate system can be devised.

#### *Suprapubic Cystotomy for Cystitis.*

Suprapubic cystotomy has been frequently performed with the object of draining a septic paralysed bladder, or when the urethra is oedematous and bleeding from catheterisation. At the time this is done the urine is infected, and is often alkaline and stinking. Two tubes kept together by a silkworm gut stitch should be introduced into the bladder, and the edge of the bladder wall may be stitched with catgut to the rectus sheath or to the skin. The double tube is used for continuous irrigation, the irrigating fluid passing down one tube and out of the other. For the first four or five days after the cystotomy, and intermittently after that, continuous irrigation should be carried out with weak antiseptic solutions such as silver nitrate (1 in 10,000), permanganate of potash (1 in 5000), peroxide of hydrogen (1 in 40 of 10 vols.), &c. It is carried out in the following manner:

A Hamilton-Irving suprapubic drainage-box is adjusted, and one of the outlet tubes is carried under one thigh and over the edge of the bed into a large receptacle. The other outlet tube may be clipped. A reservoir is hung two or three feet above the level of the patient, and from this a rubber tube passes, being interrupted just below the reservoir by a dropping-glass. The rubber tube passes through an opening in the lid of the Hamilton-Irving box and into one tube in the suprapubic wound. The other suprapubic tube acts as an outflow tube.

Continuous irrigation may be carried out day and night for four or five days, or it may be interrupted for a few hours at a time. This treatment very quickly clears up cystitis if no source of recurrent infection, such as pyelonephritis, is present. Unfortunately, in the great majority of cases in which suprapubic drainage is performed ascending infection has already taken place, and the bladder is constantly reinfected from this source. A very important question arises, however, in regard to suprapubic drainage at this stage. Is it possible, by draining the bladder, to influence the progress of pyelonephritis already established? In the advanced stage, when the symptoms of urinary septicæmia are well marked, I do not believe that any benefit will follow the operation. The progressive emaciation will continue, the anorexia and vomiting increase, and the patient die in spite of free bladder drainage. In the earlier stages, however, when the patient has passed the initial

attack, when the cystitis is well marked and he gets recurrent attacks of pyelonephritis, drainage of the bladder, by obviating the necessity of bladder washing and by abolishing intravesical tension, should prevent the recurrence of the ascending infection.

In some cases the Hamilton-Irving apparatus cannot be used, on account of the extreme flexion of the legs, and the spasmodic contraction of the abdominal and thigh muscles, set up by pressure on the abdomen.

During the first week or so, there is leakage alongside the tube in the suprapubic wound. The use of a suction apparatus such as that of Cathcart is of great value in keeping the patient dry in these cases. After this the wound contracts down on the tube, and a rubber plaque with a rubber cannula to carry the tube is strapped on over a small square of boric lint. This is retained in position by a rubber or canvas waist-band. In many cases it is sufficient to keep a No. 12 rubber catheter in the suprapubic wound and connect it by rubber tubing passing over the abdomen into a bottle lying at the side, in the hollow of the loin. A piece of adhesive plaster will keep the tube from slipping, and no leakage occurs alongside.

## A METHOD OF CONCENTRATING ENTAMOEBA CYSTS IN STOOLS.\*

BY J. W. CROPPER, M.B., M.Sc. LIVERP.;  
AND

R. W. HAROLD ROW, B.Sc., F.L.S., F.Z.S.,  
ASSISTANT LECTURER AND DEMONSTRATOR IN ZOOLOGY IN THE  
UNIVERSITY OF LONDON, KING'S COLLEGE.

(From the Laboratories of the Royal Society of Medicine.)

### Introductory.

THE following investigations have been carried out on behalf of the Medical Research Committee and with the assistance of the Durning-Lawrence Fund, under the directorship of Lieutenant-Colonel Sir Ronald Ross.

One of the principal objects of our experiments has been the cultivation of the causative organism of amoebic dysentery, and, as is well known, the difficulties in the way of the accomplishment of this have hitherto proved insuperable, almost all observers now being agreed that the amoebae which have been successfully grown are distinct from both *E. coli* and *E. histolytica*; in fact, the genus created by Chatton and Lalung-Bonnaire,<sup>1</sup> *Vahlkampfia*, has been frequently used, especially for the culturable intestinal forms, to emphasise their distinction from these two species. In a recent communication Penfold, Woodcock, and Drew<sup>2</sup> have described a method by which they have succeeded in causing the excystation of *Entamoeba histolytica*, but they also state that they have been unable to keep the excysted amoebae alive for more than a comparatively short time, 42 to 44 hours as a maximum. This failure to obtain a successful culture they ascribe to the rapid growth of bacteria in their preparations, derived from the faecal matter not got rid of in the washings to which the cysts were subjected. The injurious influence of the products of putrefactive bacteria has, indeed, been already shown experimentally<sup>3</sup> with cultures of amoebae of the *limax* type. We have therefore since then devoted a considerable amount of time to the attempt to devise a method of completely separating the cysts from the faecal matter contained in the stools.

<sup>3</sup> Cropper, J. W., and Drew, A. H.: Researches into Induced Cell-reproduction in Amoebae, McFadden Researches, vol. iv., April, 1914, John Murray, London.

Such a separation as we have just mentioned has not, so far as we are aware, been accomplished by anyone in the case of amoebic cysts, but a modification of Bass's method of concentration described by Cochran<sup>4</sup> has very nearly achieved it for helminth ova. This method consists in the preliminary emulsification of the faeces in water, and then centrifugation, after which the supernatant water is poured off, and the centrifuge tubes filled up with a 42·5 per cent. solution of calcium chloride in water, well shaken and re-centrifuged, when the eggs rise to the top of the tubes, away from the faeces and almost free from contamination.

On trying this method with *Entamoeba coli* cysts, we found that the cysts are far too fragile to withstand the osmotic currents set up by the concentrated solution, and incontinently crumple up; and a number of other chemical substances, such as syrup, glycerine, and albumin, which we have tried, have given precisely the same results, so that we feel that there is probably no specific gravity method of differentiation between cysts and faeces which will avail for entamoebæ, nor has any other method that we have yet found enabled us to achieve the complete separation of cysts and débris. We have, however, obtained a very considerable measure of success by the methods detailed below, and we are now able to obtain the cysts practically free from bacteria, and from the major part of the faeces.

The principal part of the experiments which we have carried out in investigating this method has been done with faeces infected with *E. coli* cysts, of which a constant supply has been available to us, but a sufficient series of determinations has been made with *histolytica*-infected material and with *Lamblia* infections, to show that it is equally applicable to these species, and we see no reason to suppose that any protozoal cysts would not be equally easily concentrated by it.

The technique of the method used to obtain a maximum concentration of the cysts is given first; subsequently we describe a method by which we have obtained a relative concentration without the use of any chemicals (which might possibly injure the cysts for cultivation purposes); and, finally, we describe a counting method which was devised to confirm the results of our concentration experiments.

### I.—The Maximum Concentration of the Cysts for Diagnosis.

A lump of faeces, which should be at least 1 grammme in weight, is shaken up with about 30 c.c. of normal saline (0·8 per cent. solution of NaCl) per grammme of faeces for a sufficient time to disintegrate the mass into individual particles, and thereby form an emulsion which will only settle very slowly. This is best done on a mechanical shaker in a large flask or bottle of a capacity of at least four times the amount of fluid to be shaken, and we have found it necessary, in order to obtain the best results, to continue the shaking for a minimum of half an hour.

The emulsion is then poured into a separating funnel and shaken up, by hand, for half a minute with 10 to 20 per cent. of its volume of ether (ordinary methylated ether is perfectly suitable for this), after which the mixture is allowed to stand for a minute or two in the funnel until the two liquids have separated. The faecal débris absorbs ether and consequently becomes lighter than water, and, when separation is complete, lies in a mass at the top of the saline, immediately below the excess of ether. The cysts are not affected by the ether, and consequently remain in the saline beneath.

The saline fluid is then drawn off from the separating funnel, and is centrifuged at a slow speed for two or three minutes, the precise time required necessarily depending upon the rate of centrifugation and the size of the tubes. By this means the cysts will be brought down to the bottom of the tubes with the comparatively slight amount of faecal matter not taken up by the ether.

For ordinary diagnostic purposes the concentration now effected, which should be some 15 times as rich in cysts as the original material, will be found adequate, but, if desired, a still greater proportion of cysts can be obtained by decanting the supernatant liquid and filling up the centrifuge tubes with normal saline, shaking thoroughly, and submitting the tubes to fractional centrifugation, the material brought down in the first 10 seconds being discarded,

<sup>4</sup> The Concentration of Helminth Ova from Faeces, China Medical Journal, vol. xxix., 1915.

and the whole time of centrifuging curtailed by half. By repeating this process two or three times the maximum concentration is obtained, and the débris still remaining consists almost entirely of particles of practically the same size as the cysts themselves.

The above is a concise account of the method and its results. We append a series of notes on the various processes.

It is desirable, where possible, to take a fairly large mass of faeces for concentrating, since there appears to be considerable variation in the number of cysts present in different parts of the same stool, and one of the special advantages of a concentration method is to minimise the risk of missing cysts not equally distributed.

The period given for mechanical shaking may seem extraordinarily long, but our experience is that unless the various particles of faecal matter are thoroughly washed off from the cysts the latter are removed with their adhering particles by the ether, and consequently do not appear in the final deposit. In fact, test experiments differing only in the length of time the faeces were shaken with saline showed at least twice as great a proportion of cysts in the final deposit after 30 minutes' shaking as after 15 minutes; and while in the latter case examination of the material removed by the ether showed a considerable proportion of cysts, they were almost entirely absent from it in the material shaken for 30 minutes. This length of time may, however, need to be modified in accordance with the character of the stool to be examined; our own investigations have been principally made on formed or sub-formed stools.

We have employed tap water, distilled water, and normal saline for emulsifying the faeces, and we think that saline is preferable. Whatever the method used, we have very frequently found that a considerable number of cysts have shown what we regard as osmotic collapse, their protoplasmic contents being withdrawn from the cyst wall and collected into a spherical mass about half the diameter of the cyst; but we are unable at present to determine the precise causes which have produced this result, as both the occurrence of the phenomenon is irregular and the proportion of cysts affected has varied very considerably under the same conditions. We find, however, that there tends to be a smaller proportion of cysts showing this effect in emulsions for which normal saline has been used than in tap water or distilled water emulsions from the same faeces and prepared concurrently under identical conditions. The ether employed subsequent to emulsification may be to some extent responsible, but we have more than once observed collapsed cysts in material which has not been treated with ether. In our experience this collapse does not interfere with the identification of the cysts, and we have never seen it save in *E. coli*.

We find that the proportion of the material removed by the ether varies considerably with the character of the stool used, but with an ordinary formed stool at least 90 per cent. of the weight of faeces employed is extracted. To give a concrete example, 10 grammes of faeces were emulsified, treated with ether, and centrifuged in tubes of known weight, and the deposit, after pipetting off the supernatant fluid, weighed 0.595 grammes.

Should the faeces contain fruit pips or other large heavy particles not removed by the ether it is advantageous to transfer the fluid, after treatment with ether but before centrifuging, to a tall test-tube or similar vessel and to permit the heavy particles to settle for a minute before decanting into the centrifuge tubes. The cysts themselves settle very slowly, and it has been found that the proportion which fall to the bottom with the large particles in one minute is negligible.

The time which we have found most suitable for centrifuging with 15 c.c. tubes is either 1½ minutes at 1200 revolutions per minute or 2½ minutes at 600 revolutions per minute. This will bring down practically all the entamoeba cysts from the fluid, but only a small proportion of the bacteria present come down in this length of time. In the case of lamblia a more thorough centrifuging is needed to bring down all the cysts.

The special advantages which this method possesses for diagnosis are obvious. The cysts are much more easily noticed and far more easily identified in the concentrated material than in preparations from untreated faeces. The saving of time spent in the examination of scanty or doubtful infections is considerable, and the concentrate from a comparatively large mass of stool can be examined

in a short time: there is, further, the added advantage that the possible errors attendant upon the examination of a single loopful of faeces are almost wholly eliminated. This is especially useful in the case of suspected infections in which the ordinary preliminary examination has given a negative result, and we think the method will also prove to be of great value for the final examination of carrier and of apparently cured cases before discharge.

An illustration is given (Fig. 1) of the appearance under the low power of a field from a concentration prepared in this manner. A count of the original faeces, from a smear made in the ordinary way without concentration, gave 43 cysts in 117 fields under the same lens; after concentration there was hardly a field to be found in which there were not a dozen cysts, and the average number per field was between 16 and 17.

## II.—The Relative Concentration of Cysts for Cultivation.

We feel that there are distinct disadvantages in the use of ether for treating material to be employed for cultural purposes, as the prolonged contact of the cysts with ether and with ether-saturated water may easily have some deleterious effect, and we have consequently devised a method of concentration which does not require chemicals. The first attempt to effect this was made by filtering an emulsion of faeces in water or normal saline through very fine silk cloth, some varieties of which show microscopically a mesh which is but little larger than an entamoeba cyst. It was hoped in this way to remove all particles larger than the cysts, but in practice the meshes became clogged so rapidly with débris that no filtrate was obtainable, even with the aid of a pressure pump. The smallest mesh which can be employed satisfactorily for the filtration of faecal emulsions is about 40 $\mu$  in diameter, and the method by itself is of little value for concentration purposes. Combined, however, with subsequent centrifugalisation it forms a ready means of obtaining a large proportion of the cysts free from all particles save those which approximate in size to that of the cysts, the larger fragments being held back in the deposit of the silk and the minuter débris remaining suspended in the tubes after centrifuging.

It was found, however, that no modification of this method would give so large a proportion of cysts to débris as the ether method described above, and estimations of the number of cysts per gramme of stool, as determined from the deposit in the tubes by our method of counting, showed that they were considerably less than the actual number present in the untreated faeces, a considerable number having been lost during the treatment, so that the concentration was only a "relative" one—i.e., with respect to the nature of the accompanying débris.

As finally adopted, our method follows in most respects that used by Penfold, Woodcock, and Drew, but as it differs in certain points of importance we think it desirable to give it in full, especially in order to emphasise the necessity of these or similar measures when undertaking any routine work in an endeavour to cultivate entamoebae.

Ten grammes of faeces are shaken with 100 c.c. of normal saline in a bottle or flask on a mechanical shaker for 5 minutes to obtain a uniform emulsion. This is poured on to a layer of fine silk whose mesh is of the size mentioned above, and which is stretched on a tambour (such as is used by milliners), and the emulsion is gently and continuously stirred with a glass rod to prevent the clogging of the meshes of the silk. The residue left on the filter consists chiefly of large lumps and stringy matter, and is discarded. It contains only a small percentage of cysts, which can be still further reduced, if required, by washing. The filtrate (or a portion of it) is then centrifuged for one minute at a speed of 1200 revolutions per minute, the supernatant liquid poured off, and the volume made up again with normal saline. The tube is then well shaken, and again centrifuged as before. This process is repeated until the supernatant liquid is almost clear. Finally the deposit is shaken with 10 c.c. of normal saline and is allowed to stand for a few minutes. The upper portion is then poured off and is thoroughly centrifuged, and loopfuls of the deposit are used to make hanging-drop preparations for culture experiments. An illustration (Fig. 2) is given of a high-power view of the appearance of cysts and débris in such a preparation.

By this means cysts are obtained which have been thoroughly washed free from toxic bacterial products, acid substances, and other deleterious matter present in the original faeces. The cysts can be found easily with low

powers of the microscope, and are not subsequently lost, even though it is necessary to keep the preparations for several days in the incubator. *Amoeba limax* cysts submitted to this process have been subsequently cultivated without difficulty, and were evidently unaffected either by the shaking or the centrifugation.

It must be noted that the length of time, and the speed, of centrifuging considerably affect the percentage of cysts in the final deposit; and we have selected one minute at 1200 revolutions per minute as giving the best practical results. Apparently about two minutes is required to carry down all the cysts, but a much greater proportion of the finer particles of faecal matter and bacteria accompanies them than when centrifugation is confined to the shorter time. An additional method of removing any large particles that may still be present is afforded by centrifuging for 15 seconds at 600 revolutions per minute, decanting the fluid into other centrifuge tubes and re-centrifuging for one minute at 1200 revolutions per minute; the larger particles are brought down during the preliminary 15 seconds with but a very small proportion of the cysts, and this process, repeated four times, results in the larger débris containing only one-tenth of the proportion of cysts present in the original faeces.

We have not been able to separate the cysts from débris to any further extent except by picking off a single cyst in a capillary tube, which is a comparatively simple matter in the case of *E. coli*, and has been done repeatedly in our experiments.

### III.—Method for Counting Entamoeba Cysts in Stools.

In THE LANCET of June 10 h, 1916 Miss Annie Porter<sup>6</sup> described a method of counting lamblia cysts in stools by means of a Thoma-Zeiss haemacytometer. Finding the volume of the chamber too small for counting entamoeba cysts, owing to their comparative scarcity—viz., about 1 cyst per 400 squares in an ordinary degree of infection—we devised the following method, which is described in the stages in which it is carried out.

A uniform emulsion of 10 grammes of stool (selected from several different portions of the bulk) is made in 100 c.c. of normal saline (i.e., 10 per cent. weight + volume) by shaking on a mechanical shaker for 10 minutes. All soft masses are broken up in this way, and the sediment which falls consists only of gritty particles, the so-called "false sand," which microscopic examination shows to contain no cysts.

A capillary pipette is made and is calibrated to deliver 20 c.mm. in a length of about 2 inches. It is provided with

being retained in a pipette made according to the above instructions when the mixture is blown out: in fact, we have not yet found a single cyst in the washings out after use.

Several glass slides, 3 inches by 1½ inches, having been prepared with a ring of vaseline 1 inch in diameter, a measured volume (20 c.mm.) of the emulsion of faeces is drawn into the pipette and is placed in the centre of the ring.

A cover-slip ruled in squares, such as is used with Böttcher's slides, is then allowed to fall gently, with the engraved face lowermost, flat on to the drop of emulsion, and, if necessary, is pressed down to diminish the depth of the layer of liquid. The count is made with a low power. The cysts which happen to be in any portion of the drop which extends beyond the squares are easily counted, and are indicated in the count by the letters A, B, C, &c. The squares themselves are numbered as shown (the reverse way up) in the diagram (Fig. 3).

We have made sufficient experiments to establish the utility of the method for counting entamoeba cysts in faeces, and we see no reason why its employment should not be extended, with such modifications as are found necessary, to the counting of other protozoa, either in their natural surroundings or under different conditions of cultural environment.

It has been pointed out to us by Sir Ronald Ross that in counting methods there are considerable statistical errors, the magnitude of which depends, roughly in an inverse ratio, on the actual number of things counted. Thus it is necessary to count a fairly large number of cysts in order to reduce the error to a reasonable percentage, and the present method has been devised to render this possible. The statistical tables compiled by Ross and Stott<sup>6</sup> show, for example, that if only 68 cysts are counted the probability is 9 to 1 that the error does not exceed 20 per cent., and that, if the error is required to be within 10 per cent., 271 cysts must be counted. It is advisable, therefore, to use an emulsion for counting purposes as thick as possible, consistent with ability to recognise the cysts without difficulty.

For counting *E. coli* cysts we find a 1 in 10 emulsion the most suitable, and in an average infection we count 100 cysts. With *Entamoeba coli*, as in Miss Porter's cases of *Lamblia* infection, there are considerable daily variations in the number of cysts present in the stools, ranging in a case we have been studying from 1500 to 60,000 per gramme.

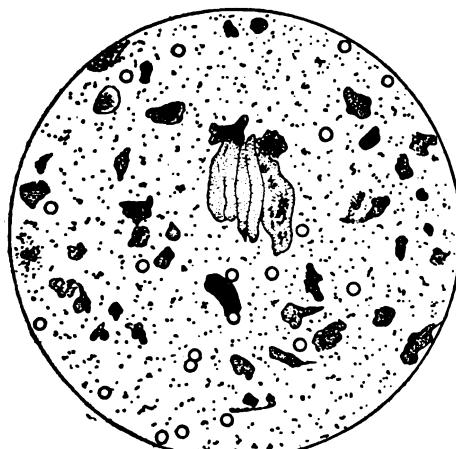

#### Summary.

1. Methods of concentrating entamoeba cysts from faeces are described, suitable for diagnosis and

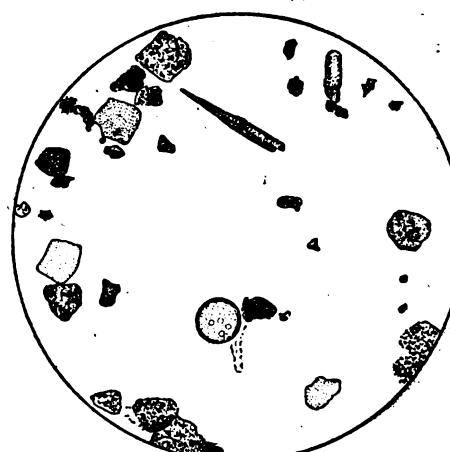

cultivation experiments respectively.

2. A very high concentration, suitable for diagnosis, has been obtained by emulsifying faeces and treating the emulsion with 10 to 20 per cent. of ether. This removes the greater proportion of the faecal matter, while the cysts remain in the saline used for emulsification, and are collected by subsequent

a rubber teat. It is well to have several of these pipettes ready to hand, so that successive counts can be made with a dry one without any unnecessary delay. The pipette supplied with Gowers's haemacytometer, and other similar ones—which are on the market, can be used for the purpose, but they have a somewhat narrow bore and frequently become clogged with débris. There is little risk of any cysts

centrifugalisation with but little accompanying débris. 3. A second concentration method is described which does not necessitate the use of ether, and which is therefore more suitable for preparing cysts for cultivation experiments. This consists of filtering the emulsion through silk, and subsequent fractional centrifugalisation. 4. The difficulties in the way of enumerating entameba cysts are discussed, and the method found most suitable, by means of the cover-slips used with Böttcher's slides, is described.

### A CASE OF SUPPURATIVE MENINGITIS WITH GLYCOSURIA SIMULATING DIABETIC COMA.

By FRANK E. TAYLOR, M.D., B.S. LOND.,  
M.R.C.P. LOND., F.R.C.S. ENG., D.P.H. CAMB.,

PATHOLOGIST AND BACTERIOLOGIST TO THE QUEEN ALEXANDRA MILITARY HOSPITAL, MILLBANK; LECTURER ON BACTERIOLOGY, UNIVERSITY OF LONDON, KING'S COLLEGE;

AND

W. H. MCKINSTRY, M.B., C.M. GLASG., D.P.H. LOND., TEMPORARY CAPTAIN, R.A.M.C.

ON Oct. 13th, 1916, the following case was admitted into the Queen Alexandra Military Hospital, and was thought worthy of being placed on record on account of several interesting points to be discussed later.

Second Air Mechanic A—, of the R.F.C., aged 36, with four months' service, had been ill for 24 hours, complaining of severe pain in the right side of the chest, cough, and difficulty of breathing. On admission the patient appeared ill, with flushed face and marked dyspnoea. The temperature was 102° F., the pulse-rate was 112, and the respirations were 38 per minute. Examination of the chest revealed diminished expansion of the right lower chest, with stony dullness and absence of tactile vocal fremitus and breath sounds of the right lower lobe. Typical "rusty" sputum was being expectorated, and the case was diagnosed as one of pleurisy and pneumonia. Poultices were applied to the chest. Calomel gr. iii. and pulv. ipecac. co. gr. x. were ordered *statim*.

Oct. 15th: The patient had had a bad night. Pain was intense, so that he could not lie comfortably in bed. The temperature still ranged from 101° to 103°. The pulse was of good quality, with a rate of 100. The respirations were very rapid, rising to 60 per minute. The physical signs in the chest remained the same, no signs of fluid being present. There was no cyanosis. The heart and pericardium were normal. The application of leeches to the right side of the chest caused great relief of the pain almost immediately, and a stimulant expectorant mixture was prescribed. Oct. 16th: Patient appeared to be greatly improved, said he felt quite well, and was very cheerful. The temperature was 102°, pulse 100, and respirations 36. There was very little cough and no expectoration.

Oct. 17th: The ward sister noticed some twitching of the patient's face; he had previously complained of intense headache. He vomited immediately afterwards and became very collapsed with incontinence of faeces. Coma rapidly supervened, with dilated pupils which did not react to light. Conjugate deviation of the eyes was noted first to the left and then to the right. All the superficial reflexes except the conjunctival were lost. Later he became very restless, constantly picking at his face, which wore a perpetual frown. The respirations rose to 64 and presented the appearance of air-hunger. The pulse still remained of good quality, being 100 to the minute. He had retention of urine, and a catheter was passed, drawing off 20 oz. On examination this contained a trace of albumin and a few hyaline and granular casts, as well as a large amount of sugar (not estimated quantitatively), but acetone and diacetic acid could not be detected. No distinctive odour of his breath could be recognised by any of several observers who examined him with this in view. Further, no history suggestive of glycosuria—excessive thirst, wasting, or polyuria—could be elicited on cross-examination of his wife; his health before this attack seemed to have been very good. An attempt made to administer alkalies subcutaneously was unsuccessful on account of the patient's restlessness, and rectal salines met with no better results. He could not take anything by the mouth. His condition remained much the same during the night.

Oct. 18th: The respirations were now 80 and the pulse 144, and inclined to be irregular. His colour had much improved. The pupils were no longer dilated. He appeared to be temporarily paralysed on the left side, and had conjugate deviation of the eyes to the left. Incontinence of urine now

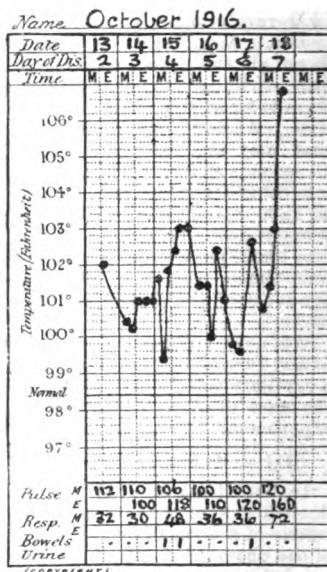

developed, but a sample of urine was collected and found to be quite free from sugar, whilst the quantity of urea present was normal. Venesection was performed, 20 oz. of blood being removed, and two pints of normal saline containing 1 per cent. soda bicarb. were injected into the vein. Later the eyes became deviated to the right, the pulse got weaker, Cheyne-Stokes respiration developed, the colour became cyanosed, spasms of the jaw and muscles of both arms were noted, and the patient died at 3 P.M. Just before death the temperature rose to 107°. The temperature chart is here shown.

A post-mortem examination was made 36 hours after death. The body was well nourished and showed no signs of external injury except a haematoma about the size of the palm of the hand between the umbilicus and left anterior superior spine of the ilium. Thorax: The whole of the pleura covering the right lung was covered with a layer of semi-membranous purulent exudation about a quarter of an inch thick, which could easily be peeled off. The left lung and pleura appeared healthy. There was no free fluid in the pleural cavity. The heart appeared normal and there was no pericardial effusion. The vessels about the base of the heart and the structures in the mediastinum were normal. Abdomen: All the organs, including the kidneys and liver and pancreas, appeared healthy. Brain: On removing the outer coverings of the brain pus was found mapping out the sulci on the anterior, superior, posterior, lateral, and internal surfaces, and also following the course of the blood-vessels. When the brain was removed the base was found free from pus except for a small area on each side where the middle meningeal artery takes its origin. The upper surface of the cerebellum was thickly covered with pus, particularly in the region adjoining the mid-cerebrum. The other surfaces of the cerebellum were free from pus. No pus could be found about the medulla. The brain when cut into showed no sign of abscess or excess of fluid in the ventricles.

Smears taken direct from the pus in the sulci, stained by Gram's method, showed long chains of streptococci as well as staphylococci. Streptococci were also found in smears from the cerebro-spinal fluid and in the blood drawn direct from the seared heart. Media of agar, broth, and trypsin legumin agar inoculated from the blood and the pus from the brain and pleura, incubated at 37° C. for 24 hours and examined, showed growths of streptococci, *Staphylococcus aureus*, and a large Gram-positive sporing organism, the last being, no doubt, due to post-mortem invasion of the tissues.

Although the nature of this case was plainly revealed by the post-mortem examination, the recognition of the cause of the sudden coma formed a difficult and perplexing problem during life. It was in the attempt to settle this question that the urine was sent for examination, and when it was found that it contained a large quantity of sugar the diagnosis of diabetic coma was raised. The absence of polyuria and of acetone and diacetic acid in the urine, as well as the absence of the characteristic sweetish acetone-like odour of the breath, rendered this diagnosis a very questionable one.

The question of uræmic coma was next raised, seeing that albumin, though in small amount, as well as a few hyaline and granular casts were found in the urine. The determination of the percentage of urea was then suggested, and for this purpose a further specimen of urine was obtained on the following day. The percentage of urea was found to be normal (i.e., 2 per cent.), and this fact was taken as disposing of the diagnosis of uræmic coma. A quantitative determination of the sugar was then decided upon, but in this specimen no trace of sugar or other Fehling reducing substance could be obtained, showing that the glycosuria was

Temperature chart showing rise of temperature to 107° before death.

only a transient condition. Lastly, the terminal hyperpyrexia, the temperature rising just before death to 107° F., which occurs not uncommonly in infective conditions, is an interesting point to note.

As regards the relationship between diabetic coma and the presence of the acetone-bodies in the urine, Cammidge<sup>1</sup> states that "all cases of diabetes are not complicated by acetonaemia, although it is a constantly present menace, since a deficiency in the oxidative process of the body is an essential element of the condition. It is only when this reaches a certain stage that the acetone bodies appear in the urine as a necessary consequence." Further, he states the acetone and aceto-acetic acid, though usually present in the urine when the coma supervenes, are not so abundant as before, but that the amount of beta-oxybutyric acid is generally much increased.

The completed history of the case, with its transient glycosuria, indicates the neurogenous origin of the glycosuria. Regarding this condition, Cammidge<sup>2</sup> states that "such a transitory glycosuria, apparently of central origin, has been noticed in connexion with lesions of both the central and peripheral nervous system, such as tumours and haemorrhages at the base of the brain, lesions of the floor of the fourth ventricle, cerebral and spinal meningitis, concussion of the brain, fracture of the cervical vertebrae, tetanus, and sciatica. It has also been met with after epileptic, hystero-epileptic, and apoplectic seizures, in traumatic neuroses, such as those following railway accidents, mental shocks, mental strain, worry, fatigue, and great anxiety."

The practical lesson which this case enforces is the danger of concluding that the presence of sugar in the urine of a comatose individual is necessarily due to diabetes. Further investigations and a critical survey of the history of such a case are essential for the accurate elucidation of the cause of the condition.

We have to thank Captain H. S. Morton, R.A.M.C., for the clinical history of this case, and Surgeon-General J. Dallas Edge, C.B., A.M.S., commanding the Queen Alexandra Military Hospital, for permission to publish it.

## THE RECURRENT TYPE OF "TRENCH" FEVER IN MESOPOTAMIA.

BY C. F. COOMBS, M.D. LOND., M.R.C.P. LOND.,  
CAPTAIN, R.A.M.C. (T.C.); LATELY ATTACHED TO INDIAN EXPEDITIONARY  
FORCE "D."

THE following case came under my observation recently at Amara, in Mesopotamia.

The patient, an officer aged about 36, was employed at the advanced base and had never been to the fighting line; he had been pulled down a little by one or two attacks of diarrhoea. Towards the end of April he had an attack of fever lasting two or three days, unaccompanied by rigor, and almost certainly not malarial. It seemed to belong to the category of short fevers, of which there were many examples in Amara. These attacks were generally traceable to exposure to the sun, which was beginning to get hot at that time. In this case the fever passed off, leaving the patient perhaps a little more vulnerable to the sun than before, but without definite sequelæ. Soon after a small degree of foot-drop developed in the right foot, with some anaesthesia of the dorsum of the foot, but this did not seem to have any direct connexion with the febrile attack which had preceded it.

About the middle of May, after a day of premonitory malaise and depression, the temperature ran up one afternoon to 103° F. and over. There was some mental excitement, the back and head ached, and the fall of temperature which soon followed was accompanied by a drenching sweat. After a couple of days in bed the patient returned to duty, but felt very tired and slack. Just a week after this last febrile attack another one developed. The fever was not so high, but it lasted two or three days. The pains accompanying it in back and limbs were more pronounced. Four similar attacks followed at intervals of exactly six days. Each attack exhibited a little less fever and a little more prostration than those which preceded it. In the later ones the pains were more pronounced, especially in the shins and tarsal bones. These pains were much aggravated by walking, and at night they were sometimes severe enough to

prevent sleep. Latterly they tended to persist after the febrile bout was over. Possibly there was a fifth attack, but if so the rise of temperature was slight. As it occurred, if at all, during transfer from one hospital to another, this slight rise may have been overlooked.

In all, therefore, there were six pyrexial bouts. None of them were marked by definite rigor. There was always a day of premonitory discomfort. During the two earlier aphyrexial intervals the patient felt comparatively fit, but each returning attack, though in itself less severe, induced a progressive loss of strength and flesh, the latter amounting in all to nearly one quarter of the total body weight. He became very pale and a little short of breath on exertion. The pulse was persistently quickened. The bowels were constipated and the urine normal. The foot-drop already alluded to cleared up slowly with the rest in bed.

The blood was examined several times. No spirilla or other protozoa could be found. Cultures were negative and agglutination results equivocal. There was a mild polymuclear leucocytosis between the fifth and sixth attacks.

Many suggestions were offered as to the diagnosis. My own view was that it might be one of the spirillar group of relapsing fevers, but this was negatived by the blood examinations, made by no less an authority than Major F. P. Mackie, I.M.S., whose researches into these diseases are well known. Captain Jamieson, R.A.M.C., recognised the similarity of the symptoms to those which had been described in Flanders under the heading of "trench fever." I was not at that time familiar with this syndrome, but since returning to England and being transferred to France I have seen a number of cases of a recurrent fever which closely resembles the pyrexial illness described above.

Two other cases of a similar fever came under my notice in Mesopotamia, but I have no satisfactory notes of them. In none of the three cases was any treatment effective save evacuation from the country into a cooler climate. This corresponds with general experience of the disease: nothing does much good except rest, plenty of food, and all the other ordinary means of increasing resistance to infection.

The causation is obscure. That the climatic factor may be ruled out is proved by the occurrence of the disease in Mesopotamia, in the Balkans, in the British armies in Flanders and in the French armies in the field, and in the troops on the Volhynian front. So far as the biting insect factor is concerned, Mesopotamia is certainly one with the other war areas; except that there are added various other torments of this description to those which usually adorn the person of the soldier in the field. The whole problem is well worthy of investigation, as the disease may inflict prolonged invalidism on the soldier. Fortunately there do not appear to be any permanent sequelæ.

## A PRELIMINARY CONTRIBUTION ON "P.U.O. (TRENCH FEVER)."

BY F. C. DAVIES, M.B. CAMB., M.R.C.P. LOND.,  
CAPTAIN, R.A.M.C. (T.C.); TEMPORARY OFFICER IN CHARGE, MEDICAL  
DIVISION, NO.—GENERAL HOSPITAL;

AND

R. P. WELDON, L.R.C.P. & S. IREL.,  
CAPTAIN, R.A.M.C. (T.O.); PATHOLOGIST, NO.—GENERAL HOSPITAL.

ALMOST the only real contribution to our knowledge of this disease, somewhat unfortunately termed "trench fever," which has been published, is contained in the report of the very careful and valuable work carried out under the guidance of Colonel Sir Wilmot Herrington, R.A.M.C., by Captain J. W. Mcnee, Captain R. J. Arundel, Captain Renshaw, and Captain E. H. Brunt. Stated briefly, they have told us that this disease is almost certainly due to an organism which is probably contained in the red corpuscles of the infected persons and that the corpuscular elements of the blood alone are capable of containing and transmitting the disease. This valuable discovery is quite in accordance with what one would expect, judging by the clinical characters so markedly shown in typical cases, and which, in certain respects, are not unlike attacks of malaria. In the main, one would outline these as follows: Sudden onset occasionally with chill. Onset with indefinite but well-marked weakness and malaise, frequently indescribable so far as the patient is concerned, who, when pressed to an extremity in so many instances says, "Well, my legs would not hold me."

<sup>1</sup> Cammidge, P. J.: Glycosuria and Allied Conditions, p. 214. London: Edward Arnold, 1913.

<sup>2</sup> Loc. cit., p. 169.

Pyrexia, severe or slight, irregular, tending to intermit, and with a well-marked suggestion of periodicity of from two or three to five days. Pains, characteristically lumbar, head or legs, all or any, at onset, "shins" later and with extraordinary consistency; vomiting may occur. In character the pains are best exemplified in these so-called "shin pains" and are of a severe boring character and neuralgic in type, being very frequently associated with marked tenderness of the nerves of the calf, including the external popliteal where it passes round the neck of the fibula, where it is frequently exquisitely tender to pressure. The pains are not necessarily confined to the shins, but may extend above the knees as far as the thighs, *missing the joints*.

Certain negative signs and symptoms of great value, when differentiating from the minor maladies, are freedom from catarrhal conditions of the upper and lower respiratory tracts, absence of dryness or furring of the tongue, even with a temperature of 102° or 103° F. The pulse is remarkably stable, and the general feeling of the patients whilst in bed is summed up best in the words they frequently used, "If it were not for this headache I should be alright," or, "If it were not for these pains in my back I should be alright"—a mental attitude which is, in the opinion of the authors unheard of in the typhoid and paratyphoid infections. The spleen is certainly not usually appreciably enlarged either to palpation or percussion. Bowel symptoms we believe not to be characteristic of the condition, though frequently amongst troops, as one would expect, one sees it associated with slight attacks of diarrhoea.

On the course of the disease we cannot speak with confidence, but it would appear that in the majority of cases at least three exacerbations of fever take place extending over an interval of *not less than two weeks*. The pains are, unquestionably, frequently severe and persistent, though not disabling. The blood shows an absence of any ascertainable growth on ordinary media. A count shows moderate leucocytosis only, with some increase of the large lymphocytes, and an absence of eosinophilia and shows no recognisable haematozoa.

One feels it necessary in describing what, to most of us, is a new disease, to emphasise the importance of taking into consideration all the aspects of the case and not to rely upon the presentation of a typical temperature chart or the presence of typical "shin pains" or any other single characteristic, a mistake which is frequently made. With this reminder we are convinced that we have in this condition a disease of undoubtedly individuality quite distinct from, and in the vast majority of cases easily differentiated from, influenza, common cold biliary attack, and myalgia, on the one hand, and the enteric group, malaria, and rheumatic fever on the other, and, in its typical instances, as easily diagnosed as any better known disease, and in its atypical cases well recognised by those who have studied such numbers of cases as the medical division of any large base hospital must provide.

With regard to treatment, it would not appear that any remedies yet tried have materially modified the course of the disease, and this fact combined with the leakage of men which the wide prevalence of the disease appeared to us to cause, led us to a belief in the extreme importance of prophylaxis. Our attention was thus drawn to the mode of transmission, and with the data provided by the workers already mentioned in our possession, and also the clinical fact that direct transmission in hospital appeared not to exist, it seemed to us that the direct transmission of red corpuscles must be brought about by blood-sucking parasites. The wide prevalence of the "louse," as has been so thoroughly investigated by Lance-Sergeant A. D. Peacock, R.A.M.C., led us to the belief that these pests were the guilty agents.

An experiment was therefore carried out with a view of testing the accuracy of this belief. Some score of lice were collected and starved in captivity for three days; a number of them died. Two pairs of the survivors were taken and allowed to bite, under a watch glass, two patients suffering from "trench fever" in an acute stage. After allowing them to feed for about 15 minutes their meal was interrupted, and each of us then allowed a pair to feed upon himself, strictly confining their sphere of operation by means of a securely fixed watch-glass. The one of us whose duties did not bring him into the wards subsequently, 24 hours later, allowed his pair to have a further meal on himself. Twelve days later very startling developments took place.

The characteristic symptoms manifested themselves, and he passed through a most typical attack of the condition of average severity, with the pains and other features all present. It may be further noted that the victim had not at any time been nearer to the front than the base, nor had he been subject to any previous similar condition.

The demonstration of this mode of transmission appears to be so striking in its success and of such immediate importance that we feel amply justified in giving what is an academically incomplete research on the etiology of this important disease. The probability is that a vigorous impulse to the anti-louse campaign may be given.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### ACUTE PNEUMONIA WITH HYPERPYREXIA, FOLLOWED BY HEART-BLOCK.

BY J. PORTER-PARKINSON, M.D. LOND., F.R.C.S. ENG., SENIOR PHYSICIAN AT THE LONDON TEMPERANCE HOSPITAL AND AT THE QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY-ROAD, E.

ACUTE pneumonia with severe hyperpyrexia is so rare, and recovery from this rarer still, that on that ground alone it would seem desirable to record this case, in which also the fever was followed by a high grade of heart-block.

A van boy, aged 14 years, was admitted into hospital under my care on Nov. 22nd, 1916. He was a healthy looking boy, with a good family and personal history. He had been taken ill with a rigor and fever and cough four days previously. On admission the temperature was 104° F. and at 4 P.M. it had risen to 105°. There were signs of pneumonic consolidation in the whole of the lower lobe of the right lung. The patient's general condition was good. At 7 P.M., however, the temperature, taken in the mouth, registered 110°; it was taken in the rectum by two different thermometers and found to be 110° each time. On being informed of this by telephone I ordered the immediate use of iced sponging and towels. Towels wrung out in iced water were placed over the front of the trunk, and changed in succession when they became warm, and the limbs were sponged with iced water. In this way the temperature had fallen to 101° when I arrived at the hospital. The treatment was then stopped. The general condition of the patient was good, he had not been delirious or unconscious. The pulse was 120, regular and of fair volume, and there was no sign of collapse. I ordered an ounce of brandy in warm milk. The temperature was then taken each half hour and began to rise again, and at 9 P.M. was 103·6°; the cold sponging and towelling again reduced it to 103·8°, after which it slowly fell to 101°, but next day it varied between 104° and 105°, and after this until the crisis on Nov. 27th it showed no tendency to rise to an abnormal height. The course of the illness was uneventful, until on Nov. 30th, two days after the crisis, the pulse had sunk to 44. When I saw the patient the same day it was beating at that rate at the wrist. The heart's apex was not displaced, and there were no abnormal sounds heard; but I was able to show by a paper lever over the jugular vein that the auricular rate was 88 while the apex beat registered 44. The pulse was of good volume and perfectly regular in rhythm. This passed off after 48 hours, and I regret that I was unable to procure the use of a polygraph early enough to get a permanent record. After this the pulse-rate gradually rose, and was intermittent, at first every three or four beats, but getting less and less so daily until a week later when the rate was about 80, and only very rarely could an intermittency be felt at the wrist or the apex. The signs in the lungs cleared up in the usual way, and the only other feature worth noting was that the pulse rate increased considerably when the patient was first allowed out of bed, so that his convalescence was retarded in this respect for about a fortnight.

A temperature of over 106° F. is exceedingly rare in acute lobar pneumonia but commoner in broncho-pneumonia. The percentage in the former disease is said to be 0·4, and with only one or two exceptions seems to have been fatal in all the recorded cases. The fact of recovery after the temperature twice reached an extraordinary height seems, as far as I can make out from the literature, to be almost unique.

It was found that whenever iced towels were renewed over the precordial region the pulse became markedly more feeble,

and hence on the second treatment with ice this area was omitted ; if this be confirmed in other cases it will serve as a useful warning.

With regard to the heart-block, it is known that minor degrees, such as lengthening of the a.-v. interval, may often be demons rated by the polygraph, though they cannot be detected by rougher methods ; but such a marked degree as a 2 to 1 block must certainly be very rare indeed. Though Mackenzie mentions that heart-block may occur after pneumonia, he does not state to what degree. It would seem that the poison which had such an unusual effect on the heart regulation had also an unusually severe effect on the heart muscle, impairing its conductivity as well as its strength.

#### A CASE OF FOREIGN BODY IN THE RECTUM.

BY N. S. BONARD, M.D.,

LATE SENIOR HOUSE SURGEON, FRENCH HOSPITAL, LONDON ;  
SURGICAL OFFICER, THE LONDON LOCK HOSPITAL.

I READ with much interest in THE LANCET of Sept. 23rd, 1916 the case of foreign body in the rectum related by Mr. Joseph F. Pearl. The following case may be interesting to relate in connexion with his paper.

The patient, a man aged 23 years, came to see me at the French Hospital giving the following history. Ten days previously he was in the lavatory playing, as he said, with a long piece of iron, when suddenly it disappeared. He could not find it again, so he believed it was in his rectum. During the ten days he had no special troubles or pain, but he was much upset in thinking that perhaps he might have a piece of iron in his body which did not come out. The general appearance of the patient was strange, and at first I did not believe a word of this history and took him for a maniac or a person mentally deficient. I asked him to get upon the gynaecological chair, and made a very careful examination. Externally there was no evidence of anal or perianal lesions or inflammation. By digital examination I could not feel anything abnormal, and did not cause the slightest discomfort or pain to the patient. So I came to the conclusion that he was really mentally deficient. When he was dressed again I explained to him that he was wrong and that he must give up this ridiculous idea of thinking he had a piece of iron in his rectum, and that it would be impossible to retain such a thing for so many days in his body without having any trouble. I was on the point of sending him away when he again gave me in a few words his previous history, telling me that as he could not find this piece of iron in or around the lavatory it was certainly in his rectum. He refused to give any further details, and described the body as being as long as his forearm and as thick as his little finger. Again I did not believe it, but bearing in mind the classical descriptions in medical books regarding foreign bodies which can be found in the rectum I made a second examination with all my strength, so as to examine as high up into the rectum as I could. I was not more successful than the first time, and was just going to give it up when suddenly very high up my finger went against something very hard on the lateral wall of the bowel. I lost it, and for a long time could not find it any more. I was so certain that what I came against was a foreign body that I began to think that after all the patient might be right, and I made a third examination. After a few minutes I was lucky enough to find again the hard body, but could hardly reach it with the extremity of my finger. I moved it as well as I could, and after manoeuvring with it I felt it more movable and coming slowly down the bowel. Then I could feel at last the extremity of a piece of iron exactly as the patient said. I could not appreciate the length, but as it was impossible to move it easily, I gathered it would be rather long. By moving it little by little I succeeded in getting the lower extremity near the internal sphincter, but as soon as I withdrew my finger the body was returning to its previous position against the lateral wall where it was impossible to grasp it for extraction. At last I used a gynaecological Fergusson metal speculum, and with a long forceps, after many unsuccessful attempts, I was able to extract a long cylindrical (with sharp-cut ends) piece of iron, 9*½* inches long and as thick as the little finger. I must say I was very surprised, and the patient was very pleased that it had come out. Fearing complications the patient was kept under observation for a few days but no trouble whatever ensued.

The purpose for which this piece of iron was being used by this young man need not be dwelt upon, but I record the case to put other medical men on their guard in face of an apparently improbable story.

**ERRATUM.**—In Table III. of the Analysis of Recent Cases of Tetanus (THE LANCET, Jan. 27th, p. 133) Case O.3 should read : "F.B. lodged in ilium."

## Medical Societies.

### ROYAL SOCIETY OF MEDICINE.

#### SECTIONS OF MEDICINE, PATHOLOGY, AND EPIDEMIOLOGY.

##### *Discussion on Toxic Jaundice in Munition Workers.*

A COMBINED meeting of these sections was held on Jan. 23rd, Surgeon-General H. D. ROLLESTON being in the chair.

Dr. T. M. LEGGE said that, in the early stages of the war, poisoning by dope which contained 12 per cent. of tetrachlorethane looked as though it were going to be formidable. Nineteen cases had been detected in one factory in quick succession. That the tetrachlorethane was the culpable ingredient of dope had been shown experimentally by Dr. W. H. Willcox, and the plenum system of ventilation then in vogue in the workshops was unsuitable. The danger had been combated by periodical medical examinations, installation of exhaust ventilation, and frequent changes of employment. The tetrachlorethane had now been replaced by a substitute which was safe. From first to last about 70 cases had been heard of, with 12 deaths. Concurrently, two or three cases of toxic jaundice due to T.N.T. occurred, and this form of jaundice was made noticeable. Consideration of the cases showed, as was to be expected, that to reduce the poisoning the dose must be reduced. At first only a few cases occurred, then with an intensification of the work, which coincided with the hot weather, there were more ; in the last two months of 1916 there were fewer cases again. The incidence had been where the material was used, rather than where it was made. The skin was the main channel of absorption, as shown by the occupations of those affected. A method of exhaust ventilation could only indirectly reduce the danger from skin absorption. In addition, mechanical aids to diminish the need for handling the material had been employed. Other safeguards used were alternation of employment, periodical medical examination, and cleaner working, and these, with suitable ventilation, were the chief methods of control.

Viscount CHETWYND, managing director of a large factory, wrote saying that it was in the interest of a factory that sickness should be kept down, in view of the reduction of labour. He was led to believe that poisoning was due to fumes rather than to dust. This was shown by the example of a group of men who worked covered with dust but with easy access to the air. No cases arose among them. In another group who worked where the circulation of air was poor and fumes were more evident, the incidence of cases was 9·3 per cent. With better ventilation this percentage dropped, a similar reduction being noticeable also after a gale. There were more gastric cases among women than among men, who fed themselves better. Consequently a part of the wages of the women was withheld, and they were efficiently fed ; this was followed by a reduction of cases from 11·6 per cent. to 1 or 2 per cent. Although the amount of wages withheld did not cover half the expense of feeding them, the improvement in their health made the transaction financially successful.

Professor BENJAMIN MOORE said that the minor illnesses arising from T.N.T. were of very great importance. The number of absences from this cause at one factory was high. It was his fixed belief that it could be eliminated. He had kept animals in dense fumes for considerable periods, but they remained well. He then noticed that in a very clean factory where workers had oily hands cases occurred. Next he provoked poisoning symptoms in himself by rubbing an oily preparation of T.N.T. into his palms. In a factory he had breathed fumes and dust very systematically, but had not induced any poisoning. Most poisoning occurred among the workers who rubbed off the spilt material about the shells which should never have been there. There was an attitude of false security about the handling of T.N.T. because it was so little explosive. There should be as clean working with T.N.T. as with black powder or petrol. As preventive measures cleanliness came first, then alternation of

employment. During the periods of cessation of work with T.N.T. there must be cleanliness of the skin, changing of underclothing, and cleansing of the scalp. An organic solvent such as acetone should be used to remove the material from the skin and scalp as far as possible. The greater the degree of the cleanliness observed the less would be the incidence of illness. There should be a penalty for careless handling and if the floor became littered with dust.

Dr. B. H. SPILSBURY described the post-mortem and microscopical changes found in cases of tetrachlorethane, dinitro-benzene (D.N.B.), and T.N.T. poisoning. He pointed out that in all cases the most advanced changes were found in the liver. In large areas of this organ the cells had almost or entirely disappeared, the stroma remaining, and showing in some cases processes of organisation, with fine globules of fat as sole evidence of the previous fatty degeneration of the cells. The bile-ducts in some cases remained, and might show active proliferation and even slight attempts at regeneration of the liver tissue. The areas in which the liver tissue had not disappeared might show some hypertrophy of the liver cells, but these generally exhibited a varying degree of fatty degeneration. In all cases the kidneys exhibited fatty degeneration—generally widespread and advanced—and in most cases there was fatty degeneration also of the heart muscle. Experiments in rats with the vapour of tetrachlorethane, conducted by Dr. Willcox and himself, had shown that on exposure to the vapour for one week a marked fatty degeneration of the liver developed and less of the kidneys and heart, the other organs showing no pronounced alterations. These experiments suggested that the earlier stages of tetrachlorethane poisoning in man consisted of fatty degeneration, which in the liver led to complete destruction of many of the liver cells before death.

Dr. MATTHEW STEWART spoke of the blood changes and of the microscopical appearances of the organs. His paper was published in full in THE LANCET of Jan. 27th.<sup>1</sup>

Dr. P. N. PANTON dealt with the blood changes. He had examined the blood in the case of 50 women in one factory who were still at work and apparently well. No blood changes were found except those of minor importance. The majority showed some leucocytosis, chiefly of polymorphonuclear cells. There was no suggestion of blood destruction in contra-distinction to what had been described in poisoning by D.N.B. One hundred workers had been examined for cyanosis; 18 were definitely cyanosed, others were blue, but possibly because the day was cold. The cyanosis had been generally ascribed to methaemoglobinæmia, but he did not consider that this had been proved. He had used Haldane's test, with which 36 examples of blood were positive, but the conclusiveness of the test was difficult to be sure of. Of 100 workers, in 20 the serum was bile-tinged without evidence of jaundice, but this sign was also present in a certain number of normal people. Of 19 cases of poisoning with T.N.T., 15 of whom had toxic jaundice, nothing abnormal was found in the blood in 13. Two conditions might occur, in his opinion, with T.N.T.—(1) toxic jaundice, (2) an aplastic anaemia. He had seen four cases of the latter, two with jaundice and two without it.

Dr. H. M. TURNBULL had examined post mortem seven cases of toxic jaundice caused by T.N.T. In six of these the least damage in the liver was in the anterior part of the right lobe; in the seventh the most affected portion was the upper part of the right lobe. The destruction was greatest in the parts most remote from the portal blood-supply. The condition resembled portal cirrhosis of the liver in the patches where the destruction was not complete. In some cases there was regeneration. The changes had not always been progressive. In one case a large liver was met with, showing only three very small areas of complete destruction and elsewhere reticular fibrosis. Another case was one of very severe anaemia without jaundice, and was erroneously thought to be an example of pernicious anaemia. The liver showed fatty degeneration in the centre of the lobules as occurs in severe anaemia (there was no iron), but in another part the lesions were like those of T.N.T. Two other cases of men with extremely severe anaemia were examined. They were examples of aplastic anaemia, and very little marrow was found, but in it were many plasma cells and phagocytes

containing chiefly erythroblasts. There appeared to be an actual destruction of the marrow by the poison.

Mr. I. FELDMAN raised the question of the possibility of another toxin being present in T.N.T. cases, and thought that Webster's test should not be regarded too absolutely as determining the existence of T.N.T. poisoning. He cited a case which had occurred seven weeks after the last exposure to the poison, and in which no trace of T.N.T. was found in the urine or faeces. In two animals which had been poisoned with T.N.T. no trace of T.N.T. was found in the organs, and in a fatal case the same absence of T.N.T. in the organs was met with. Among the early symptoms were a very definite dark-brown colour of the urine before jaundice was noticeable, urgency in micturition, and lassitude, the patients feeling faint and weak. A later symptom in one case was the appearance of leucin and tyrosin crystals in the urine. The metabolic activity of the liver was not affected as far as urea was concerned.

Dr. W. J. O'DONOVAN dealt with the clinical aspects. The typical manifestations could be classified into five groups: (1) Dermatitis; (2) an irritative gastritis evinced generally during the first week of employment, and cured by simple treatment and a few days' holiday; (3) a toxic gastritis; (4) effects upon the blood and blood-forming organs; and (5) toxic jaundice. Toxic gastritis was due to T.N.T. absorption; its symptoms were colicky epigastric pain, often severe, and having no relation to meals, constipation, anorexia; wasting and sometimes vomiting were associated symptoms. It was difficult to diagnose this from gastritis due to other known causes, but the wizened pallor of the face of these T.N.T. cases was very striking. Another common sign of T.N.T. absorption was cyanosis, but neither this nor gastritis were reliable warnings that jaundice might supervene. Of 30 cases of toxic jaundice, in 15 the jaundice was the first sign to call for notice. In 1916 about 50 deaths had occurred from toxic jaundice, a mortality among those exposed of 0·05 per cent. The total sickness incidence had in one factory been as high as 11 per cent., but the sickness incidence and the mortality rate in cases of jaundice had both steadily lessened. Jaundice might supervene at a very early or late period of employment, from the fourth day to the ninth month, and it might first appear after an absence up to two months of freedom from exposure to absorption. The prognosis of a case of toxic jaundice was uncertain; when recovery was expected coma or convulsions might suddenly supervene. But with the early detection of icterus the prospects of the chances of recovery were much greater. A second attack should not occur, because a return to T.N.T. work from recovery from toxic jaundice was forbidden, but he had seen one such case; in this the man after a return to T.N.T. work became again icteric and in addition very pale; the serum contained bile pigment and the blood showed a marked absence of bone marrow reaction. Since Professor Moore's investigations were reported great attention had been paid to the prevention of the possibilities of skin absorption.

Mr. J. A. P. BARNES said that an observation of 1100 workers had borne out in the main the contention that the channel of absorption was chiefly the skin. He had found that among employees working with greasy hands the incidence had been 17 per cent., as compared with 10 per cent. among others. In two groups of workers the hands were brought into close contact with the powder. Among these there were toxic symptoms in 10 per cent.; in all the others this occurred in 1 per cent., in spite of exposure to fumes in the case of some of them. He thought that the mucous membrane was also a channel of absorption in the case of women who wore suction plates, between which and the mucous membrane a sandwich of powder collected and remained all night, as the women were often advised by the dentists not to remove these plates at night. Girls, after a few days at the work, often suffered from severe mental depression; this was afterwards replaced, when serious jaundice occurred, by a state of exaltation, probably toxic, and reminiscent of the spes phthisica. He hazarded the suggestion that excretion plays a large part in the elimination of the toxicity of T.N.T. He had transferred a group of ten workers from a well-ventilated building to one less well ventilated and more confined; they deteriorated in health, while those who replaced them, coming from the worse ventilated building, improved considerably. He had endeavoured to find out whether any after-effects occurred in those who had formerly worked on T.N.T., and constipation was commonly complained of.

<sup>1</sup> In commenting last week upon this paper we alluded to 12 cases of accidental death in munition workers which Dr. Stewart had studied. In one of these distinct liver changes were found. But the main conclusions of the paper were based upon the examination of seven fatal cases of T.N.T. poisoning.

Dr. W. R. SMITH gave his experiences in a shell-filling factory. Up to Jan. 20th there had been 62 cases of toxic jaundice with 16 deaths, 10 in men and 6 in women. Six cases had occurred in youths under 18, with 4 deaths; the employment of juveniles was then stopped. There had been a steady falling off in the number of cases due to several factors, the most important being efficient ventilation. Another beneficial factor was the introduction of intervals during the shifts for relaxation, feeding, and walking about. All the women were supplied with two good meat meals daily. Thorough preliminary examination of employees had been introduced and free dental advice and treatment provided on the spot. Finally, pressure had been applied to make the cases report earlier. A most striking clinical feature was the reluctance of most cases of toxic jaundice to admit that they were ill in the early stages. No dermatitis had been met with among the jaundice cases. Nausea and anorexia were usually present early. Constipation was almost invariable. Purpura occurred in three cases; in one around the nail-beds, in one in the mucous membrane of the mouth and lips. Drowsiness and sometimes maniacal violence occurred. In one case tetanic convulsions and opisthotonus simulating cerebro-spinal fever were met with. Absolute rest in bed was essential even in the mildest cases. CaCl<sub>2</sub> might be used if there was any suggestion of hemorrhage.

Major O'REILLY said it was noteworthy that no ill-effects from T.N.T. had been noted before the war, even among juvenile workers. The cutaneous affection was most frequently met with during the first week of exposure, the hands, wrists, face, and neck, and occasionally the ankles being the chief sites. Itching occurred. It was followed by a fine desquamation and was not generally severe, but yielded to simple ointments. The toxic effects presented themselves in three forms: the gastric type (usually with cyanosis), toxic jaundice, and the anaemic type. These were not different stages, but distinct types. The gastric type occurred at all periods of exposure and was marked by listlessness, pallor, cyanosis, an icteric tinge of the conjunctive, depression, nausea, giddiness, faintness, pain behind the xiphisternum, and constipation. It was remediable by suitable treatment and left no after-effects. The chief diagnostic aids were constipation, the pallid pinched appearance, and the epigastric pain. He had not seen the toxic jaundice form emerge from the gastric form. It appeared suddenly and did not differ at first from ordinary catarrhal jaundice. The liver might be enlarged in the early stages. In three fatal cases meningeal symptoms appeared, leading to coma and death. The anaemic cases looked like examples of pernicious anaemia, but though the colour index might be high there were no nucleated red cells. Speaking of the treatment, he said that the use of acetone had been encouraging. From the point of view of prevention, great attention had been paid to the teeth, which were inspected once a week. Gloves, veils, and respirators were supplied, and change of employment given fortnightly. The workers were warned to change their clothes when at home. Milk was supplied free. Washing of hands was insisted upon, and ointment was supplied in each workshop.

Dr. MORLEY FLETCHER referred to a case of toxic jaundice under his care in hospital in which saline infusions and venesection had had no beneficial effect in contradistinction to what he had experienced in cases of acute yellow atrophy. The blood was noticed to be very tarry. He queried whether these methods had been useful in other cases and whether they should be employed in early stages. The cerebro-spinal fluid had been found bile-stained after death in a case in which it was clear during life.

Fleet-Surgeon R. C. MUNDAY, R.N., recorded his experiences in the Admiralty munition establishments. There had been a complete immunity from toxic jaundice; this he explained by the greater degree of cubic space provided, the absence of piece-work, better discipline and cleanliness, and better ablutionary arrangements. He thought it was better to remove the fumes from their source than from the bottom of the room. Alternation of work was provided very fully. Scrupulous cleanliness was observed and soiling of shell-cases was prevented. There was an absence of dust on the floors. The workpeople were clean. He agreed that the skin was the chief channel of absorption. At the naval air stations no case of dope poisoning had occurred, the alternation of work among those employed being very perfect.

Dr. EMMA C. PILLMAN said that it was difficult to state when toxic jaundice started, as 15 per cent. of women workers had yellowness of the conjunctive, probably due to constipation, before commencing work. All cases of jaundice could not therefore be notified with advantage.

Dr. MARY A. S. DEACON and Dr. H. G. P. CASTELLAIN concurred as to the frequency of bile-tinged conjunctive before exposure to T.N.T.

**2. Clinical Disorders of the Heart Beat.**

By THOMAS LEWIS, M.D. Lond., F.R.C.P. Lond. Third edition. London: Shaw and Sons. 1916. Pp. 118.

1. We welcome the second edition of this excellent little manual on "The Diagnosis and Treatment of Heart Disease." As a practical guide to examination of the heart we know nothing better. The pages dealing with treatment are also most helpful, giving a very complete outline of principles and a survey of the various remedies found by experience to be of benefit. We congratulate the author upon such a sane combination of the older methods of clinical examination and the newer introductions of the electro-cardiogram school. No doubt the explicit directions and the care spent upon the detection and elucidation of heart murmurs will seem matters of supererogation to those who regard these morbid signs as of less value in the study of heart disease than was formerly taught, but we are in agreement with the author in this matter. The section dealing with the significance of the patient's symptoms is full, as is also the account of the arterial and venous pulses; the chapter on cardiac irregularity serves as a clear introduction to this more recent branch of heart observation. Amongst many points which we read with satisfaction we note the emphasis put upon the need for searching carefully for an aortic diastolic bruit in any suspected case of aortic regurgitation, and upon the fact that such bruit is very often heard only down the left margin of the sternum. There is a useful paragraph upon "posture murmur," another upon what the author terms the "apprehensive heart," and a third upon the effects of rheumatism upon the heart in children. These are only three of many such helpful paragraphs. There is very little of criticism to say. But on p. 23 "sounds" are spoken of as being "felt"; and on p. 94, speaking of acute pericarditis, the sentence "its presence is recognised by the associated endocarditis, by some respiratory distress, and by pericardial friction," might be re-written with advantage. On p. 45 the reference (p. 46) should be (p. 37).

2. The third edition of Dr. Lewis's little work follows speedily upon the second, and the fact shows clearly the importance of, and interest taken in, the newer study of heart disease by means of special instruments. We have recently<sup>1</sup> dealt fully with Sir James Mackenzie's latest statement of his work and of his experience in this direction. Dr. Lewis's book gives the student and the practitioner a clear synopsis of the facts up to date and an exposition of current hypotheses to explain them. The author writes with a lucidity and with an accuracy in the use of words that serve to simplify what many readers find a very difficult subject. His early chapter on the common types of disorder of the cardiac mechanism and their meaning serves admirably as an introduction to the subject, and by its simplicity it coaxes the student into the more serious parts of the subject that follow. These parts are dealt with under the headings: Sinus Irregularities, Heart-block, Premature Contractions, Paroxysmal Tachycardia, Auricular Flutter, Auricular Fibrillation, and Alternation of the Pulse. The material of the book is so arranged that it is quite possible for the reader to omit any close study of the various curves which illustrate the text and still to preserve continuity in the argument. Indeed, we think this method of reading the book might be quite a good one for the student or practitioner to whom the subject of heart irregularities is

new and its nomenclature strange. The practitioner with clinical experience will have little difficulty in co-relating his own bedside and consulting-room observations with the author's admirable generalisations. At the second and later perusals of the book the technical details of the electrocardiogram tracings can be studied by the help of what is still an unfamiliar terminology. In connexion with each of the above types of disorder of the heart mechanism the author discusses prognosis and treatment, and these sections are written with the same careful clearness as are those dealing with diagnosis. We recommend the book very heartily, and we are not surprised to find that it has been in such demand as to necessitate this new edition.

#### *The Cure of Obesity and Obese Heart.*

By J. S. KELLETT SMITH, F.R.C.S. Eng. London: J. and A. Churchill. 1916. Pp. 93. Price 3s. 6d. net.

In this small book Mr. Kellett Smith has dealt fully with the principles and practice of the treatment of obesity by passive ergotherapy, more generally known as the Bergonié treatment. But although this particular method of treatment is the chief *motif* of the book, the author shows his freedom from any sort of obsession by giving due prominence to the question of diet, of voluntary exercise, and, in special cases (for the due recognition of which he gives very useful directions), of the administration of thyroid extract. Indeed, the author emphasises the importance of combining the various known principles of treatment of this particular metabolic defect. Exact details are given of the mode of application of the special faradic current used to cause the muscular contractions, and the immediate and remote effects are duly recorded. In the case of fatty heart the use of graduated exercise in conjunction with the Bergonié treatment and dietary is described fully. We cordially recommend this monograph to all practitioners who have to deal with obese subjects.

#### *Eclipse or Empire?*

By HERBERT BRANSTON GRAY, D.D. Oxon., and SAMUEL TURNER. London: Nisbet and Co., Limited. Pp. 316. Price 2s. net.

MUCH in this book may be studied with advantage. The authors' text is: "Forty years ago Great Britain was still the workshop of the world. To-day she is not"; and they show where "she is not" and why "she is not." Their arguments are familiar, and their force and truth will be recognised in intelligent circles. The facts contained in a glossary of 179 pages out of a total of 307 afford most interesting and serious reading, and disclose that a large proportion of the new ideas and inventions which have been evolved during the last 40 years have been due to other nations than our own, and in so many (too many) instances where inventions have been British their value and utility have been more greatly appreciated and supported in foreign countries than at home. This is not as it should be, and the authors' aim in bringing these facts forward is to drive the nation out of its apathy, so that we may resume that supremacy which we once held and be prepared for the alarm of peace—for the trade war which will follow the war of armies and navies. On the whole the authors make out their case with success, but occasionally they are inclined to discount the rôle of the British too heavily. Under the title of "The Healing Art," for example, they state that there is clear evidence that the new ideas, discoveries, and developments in this branch of human activity have, for the most part, had their source abroad. We do not think this is a correct interpretation of facts, even when considering their own analysis of historical developments, and the Germans, at all events, do not figure so conspicuously in the list as do other nations. The British, at any rate, may lay claim to initiative in their work on cholera, malaria, typhoid, Maia fever, cerebro-spinal meningitis, and sleeping sickness, while German investigation has borne chiefly on diphtheria and syphilis. The X-ray discovery by Roentgen, again, was based on an English vacuum tube and the dynamo was Faraday's wonderful conception. In many cases, however, it is right to claim that the superstructure of a discovery made in this country has been reared largely by German scientists. This is the main lesson for us to

learn, and we are rapidly learning it, as is shown by our increasing output of chemicals, dyes, glass, and other products formerly supplied to us exclusively by the enemy. The book is very plain in its teaching and the subject-matter should receive a widespread and careful study. It provides an interesting balance-sheet, showing fairly, on the whole, our industrial position in the world's affairs, and our position is certainly not always to our credit.

#### JOURNALS.

*British Journal of Inebriety.*—The issue for January contains an interesting and valuable article by Dr. J. W. Ballantyne on Alcohol and Ante-natal Child-Welfare. In his discussion of the subject Dr. Ballantyne, following the convenient method adopted by him in previous work, subdivides ante-natal life into three periods—the foetal period extending over seven months prior to birth, the embryonic period, comprising the earlier phase subsequent to the conjunction of the ovum and the spermatization, and the germinal period stretching away back into the lives of the parent organisms. The influence of alcohol circulating in the parental blood is different in degree in these different periods. In the foetal epoch the developing offspring has an intimate and highly specialised relationship with the mother through the placenta, which probably to some extent impedes the free access of alcohol to the fetus. Dr. Ballantyne notes that the experimental evidence regarding the filtering power of the placenta is in some points conflicting; he leans to the view of Nicloux that alcohol passes through the structure freely, but he considers that the foetal tissues at this stage are fairly resistive, so that the damage done by the drug is less than when it acts on the embryo or the germ cells. As confirming this view he remarks that clinical evidence has shown that the elimination of alcohol in the second half of pregnancy may be followed by the birth of healthy children, even to mothers whose precreative career, under the influence of alcoholism, had already shown still-births and abortions. With regard to the effect of alcohol during the embryonic period, it is difficult, from the nature of the case, to get experimental data in mammalian animals, and most of the work bearing on the question has been done in the hen's egg. The most extensive and important researches in this department—those carried out by Charles Féé—gave conclusive evidence of the power of alcohol to retard growth and to arrest or misdirect development. Presumably, it may have a similar action in mammals, including man; but in this connexion it is to be noted, as the author points out, that the embryo has some protection from the decidua membranes. More definite and important evidence is available as to the effect of alcohol in the germinal period of ante-natal life, and in discussing this point Dr. Ballantyne lays special stress on the recent work of Stockard, whose careful experiments he considers to be decisive. Stockard's results, taken in conjunction with Bertholet's observations regarding the pathological changes in the reproductive glands of drunkards and with the clinical data as to heredо-alcoholism, lead him to formulate the conclusion that alcohol produces its most serious and lasting evil effects upon the individual and the race in the germinal epoch. A very full and up-to-date list of the literature of the subject still further enhances the value of this very important paper. Comments on Dr. Ballantyne's article by some members of the Society for the Study of Inebriety are also given.

**BRIGHTON HOSPITAL SUNDAY.**—The balance-sheet of the Hospital Sunday collections in Brighton, Hove, and Preston shows that the total received amounted to £1005 8s. 4d., as compared with £1007 6s. 4d. in the preceding year. In the allocation of the fund, the Royal Sussex County Hospital received £432, the Dispensary £118, and the Children's Hospital £90, ten other charities also participating.

**HASTINGS AND MENTALLY DEFECTIVE CHILDREN.**—It is satisfactory to find that the municipal authorities at Hastings are proceeding with their schemes, which were initiated in pre-war days, for the care and education of mentally defective children. A special school has recently been opened at Hastings which provides accommodation for 40 children, and those who are being specially catered for are the feeble-minded and those who are feeble because of their physical condition or the surroundings in which they are brought up.

# THE LANCET.

LONDON: SATURDAY, FEBRUARY 3, 1917.

## Infective and Toxic Forms of Jaundice.

IT is familiar knowledge that some forms of jaundice may occur under epidemic conditions, and as long ago as 1886 WEIL described the form of febrile jaundice associated with nephritis and splenic enlargement which has been generally regarded as the type of infective jaundice. But before this, in 1866, WEISS had described an epidemic as one of "infective jaundice," and even earlier the French school of pathologists had recognised the infective character of some of the conditions in which jaundice was the prominent symptom. Dr. A. F. HURST calls attention to this early French work in a letter in our columns this week. War often serves to spread epidemic disease and so to afford special opportunities for observation and research. In the South African War epidemic jaundice occurred among our troops, but it was variously regarded by different observers, some describing it as infectious, while others attributed it to gastro-intestinal catarrh. In the present war pathological work has been pursued far more systematically, and recently some interesting and important observations have appeared which have served to enlarge considerably our knowledge of the etiology of jaundice, and which therefore merit careful study. An interesting record of observations upon cases of infective jaundice was given in THE LANCET of Jan. 27th by Captain A. STOKES, Captain J. A. RYLE, and Captain W. H. TYTLER, and a careful analysis of 178 cases appears in the *Quarterly Journal of Medicine* (vol. x., Nos. 37 and 38) by Colonel Sir BERTRAND DAWSON and Lieutenant-Colonel W. E. HUME. In both papers due acknowledgment is made to the work of a group of Japanese observers, Drs. INADA, IDO, HOKI, KANEKO, and ITO, who, from the study of a disease associated with jaundice, haemorrhages, and albuminuria occurring under endemic and epidemic conditions in the western part of Japan, first demonstrated the presence of a spirochete as the causal agent. Their observations seem to be amply confirmed by the British observers, and there can be no doubt that, at any rate, some of the cases occurring among our soldiers in Flanders are identical with the disease investigated by the Japanese authors.<sup>1</sup>

The general clinical features of the condition are clearly delineated in both of the papers to which we have referred. Captain STOKES and his co-workers describe the onset as strikingly uniform,

being acute, often ushered in by a shivering fit, and accompanied by vomiting, headache, and pains in the back and limbs. There is generally fever varying between 103° and 105° F., and often great prostration and lassitude. Jaundice seems to appear usually on the fourth or fifth day of the illness, and becomes progressively deeper until the ninth or tenth day, after which, as a rule, it fades rapidly. The tongue is dry and brown in colour. Vomiting, which is almost constant in the early stages, is frequently bilious and sometimes blood-stained. Constipation seems to be the rule in the disease, and the stools are usually bile-stained, while labial herpes occurred in 42 per cent. of the cases and invariably became haemorrhagic. Other haemorrhages seem to occur frequently, at any rate in severe cases, giving rise to haematemesis, haemoptysis, epistaxis, and occasionally purpura. The urine is very deeply coloured as a rule, and albuminuria is almost constant, varying from a faint trace to a considerable amount. Microscopical examination shows tube casts and red blood corpuscles. In the more severe cases torpor was noticed, progressing to the typhoid state and accompanied by rambling delirium. The account given by Colonel Sir BERTRAND DAWSON and Colonel W. E. HUME is identical in almost all respects with that given by Captain STOKES, except that a gradual onset was more often noted by the former, especially in mild cases, and the liver was more frequently found to be definitely enlarged. An interesting account of the morbid anatomy illustrated by admirable plates is given by Sir BERTRAND DAWSON and Colonel HUME. The mucous membrane of the duodenum in fatal cases was found to be oedematous, congested, and dark blue in colour. There was usually swelling round the orifice of the bile duct, but the ducts themselves presented the natural appearance. Though some changes were found in the liver by Captain STOKES, they do not appear to be present as a rule. In 1914 INADA and IDO demonstrated the presence of a spirochete in the livers of guinea-pigs infected with the blood of patients suffering from the disease, the animals developing jaundice with pyrexia and albuminuria. Afterwards they showed the presence of the same spirochete in the blood of patients and in the tissues of some fatal cases. They also proved the presence of protective substances in the blood serum of patients recovering from the disease. Their observations suggest that in the early stages the spirochete is in the blood stream, but that after the fifth day it gets more inconstant as the development of immune substances in the blood proceeds. After the tenth day they found the spirochete in the urine, whence it has been recovered as late as the thirtieth day. They were of opinion that the portal of entry of the spirochete was the alimentary canal, but admitted that there was a possibility of infection occurring through the skin. Subsequently they were able to cultivate the spirochete outside the body. Practically all these observations have been amply confirmed by the British observers, as well as by Dr. L. MARTIN and Dr. A. PERRITT in the French Army, who demonstrated further that the incubation period in an

<sup>1</sup> The case for the spirochete as causal agent of infective jaundice is strengthened by a successful attempt of some of the same Japanese investigators, described at p. 192, to apply the principles of passive immunisation to the treatment of the condition.

accidental infection of one of their colleagues was six to eight days. So far, Captain STOKES and his co-workers have not been able to grow the spirochæte outside the body. Some recent observations by the Japanese observers, also confirmed by Captain STOKES, suggest the possibility of the field rat being an agent in the spread of the disease.

Since the outbreak of war the occurrence of toxic jaundice in munition workers has drawn special attention to another form of jaundice, and recently a discussion on this subject has been held at a combined session of the Sections of Medicine, Pathology, and Epidemiology of the Royal Society of Medicine, of which a report appears in the current number of THE LANCET. Toxic jaundice is a well-recognised condition and one form of it—namely, that due to phosphorus poisoning—has been investigated extensively by toxicologists, physiologists, and pathologists. The haemolytic nature of some cases of toxic jaundice was established by the experiments of STAEDLMANN and W. HUNTER with tolulylene diamine. In 1915 Dr. W. H. WILLCOX and Dr. B. H. SPILSBURY recorded their observations upon an outbreak of toxic jaundice of a new type amongst aeroplane workers.<sup>2</sup> They proved that this condition was due to tetrachlorethane used in a dope or cellulose varnish. Dr. SPILSBURY's observations upon two fatal cases, and upon the condition experimentally produced in animals, demonstrated that there was a toxic fatty degeneration of the liver, starting in the central zones, then spreading through the lobules, and leading to necrosis. This was followed, if the patient survived sufficiently long, by replacement fibrosis. Fortunately, the occurrence of this condition has now been entirely prevented by appropriate measures and by the use of a safe substitute for tetrachlorethane. A condition of similar character has, however, been observed in some workers with trinitrotoluene. Several of the speakers at the discussion at the Royal Society of Medicine pointed out that the symptoms of poisoning by this substance comprised early cutaneous irritation and dermatitis, toxic gastritis, aplastic anaemia, and toxic jaundice. The blood changes were carefully described by Captain MATTHEW J. STEWART, whose remarks were published in full in last week's issue of THE LANCET. The most striking feature is a neutrophil leucopenia, due, presumably, to a progressive failure of the leucoblastic function of the bone marrow. In one case Captain STEWART found a neutrophil leucocytosis; lymphocytosis was present in many cases, eosinophilia in a few. The changes in the erythrocytes and haemoglobin were less marked as a rule, but in three cases the anaemia was of the pernicious type. The changes found post mortem in the liver in fatal cases were similar to those previously found by Dr. SPILSBURY in tetrachlorethane poisoning. Captain STEWART describes them as being of a character between a subacute yellow atrophy and an ordinary multilobular cirrhosis of irregular distribution.

In both of these conditions, the spirochætal infection and the trinitrotoluene poisoning, it is

important to notice that jaundice is not an essential or invariable symptom. The spirochætal form of jaundice appears to be a true obstructive jaundice due to swelling and partial occlusion of the bile papilla, but both Captain STOKES and his co-workers, as well as Sir BERTRAND DAWSON and Colonel HUME agree that cases of spirochætal infection can occur without jaundice. The latter observers deprecate the use of the term "Weil's Disease" for the spirochætal form of jaundice, since they point out that other forms of infective jaundice occur and that in the disease described by WEIL the infective agent is believed by some authorities to be the *Bacillus proteus fluorescens*. It seems to us that their objection is well founded and the alternative name Spirochætosis icterohæmorrhagica is preferable, in spite of its somewhat cumbersome character. The toxic forms of jaundice here considered seem clearly to belong to the haemogenous group, and again it is important to remember that poisoning by these toxic substances may occur without jaundice. A recognition of the facts shows that a wider view of both conditions must be taken if satisfactory diagnosis is to be expected, and that too much attention must not be paid to the factor of the jaundice. We can commend the papers to which we have referred to our readers for careful study, since they contain much interesting information and many useful suggestions in regard to diagnosis and treatment.

### Gunshot Injuries of the Spinal Cord.

In the Bradshaw Lecture recently delivered before the Royal College of Surgeons of England, and published in THE LANCET of Jan. 20th, Colonel CHARTERS J. SYMONDS, A.M.S., took for his subject the surgical treatment of gunshot injuries of the spinal cord, and dealt in an interesting manner with an important theme. For every surgeon who has had much to do with the treatment of the wounded in the present war has found out the dismal fact that there is no other injury of any organ of the body which approaches gunshot injuries of the spinal cord in the rate of mortality, and this is especially evident when we consider not only the deaths which occur within a short time of the infliction of the injury but especially when we take into account those resulting from complications which may not ensue until weeks or months after the infliction of the injury. The latter aspect of the subject has been fully dealt with by Mr. J. W. THOMSON WALKER in a Hunterian Lecture, delivered before the same College and published in our columns this week. It is a valuable contribution, and contains suggestions for the avoidance of fatal renal infections which command attention.

The injuries which the spinal cord may suffer vary from a mere bruise to complete severance, and the symptoms and treatment will therefore vary in the very greatest degree. It is fairly well established by now that a bullet may cause concussion of the cord with complete paralysis of all the nerves given off below, even though the bullet has never come in contact with the

<sup>2</sup> Med. Soc. Trans., 1915, xxxviii., 129; THE LANCET, 1915, i., 544.

cord; fortunately, in these cases the rule is that complete recovery follows. The fear of meningitis restrains many surgeons from dealing as freely with injuries of the cord as they otherwise might, but it is strange how little a tendency there is to the production of spinal meningitis, even in cases where suppuration is present and where a puncture in the dura mater exists. There may be a discharge of cerebro-spinal fluid for days or weeks, and yet no meningitis may occur. Only it is essential that there should be good drainage, so that there may be no tension—if the wound be closed or ill-drained meningitis is likely to follow. Therefore the mere presence of sepsis in a wound need not prevent the surgeon removing fragments of bullets or shell from the neighbourhood of the cord, even when the dura mater has been perforated. In such cases an early operation provides for the removal of the foreign body and for thorough drainage of the wound. When, in injury of the spinal cord, it is clear that there is complete loss of continuity of the cord, the wound having healed, any operation to remove fragments of bullets or shells is, as a rule, absolutely useless. There is, however, one exception to this rule, and that is when the pressure of the piece of projectile or displaced bone is causing pain. The relief of pain following operation may sometimes be exceedingly great, and a patient who has needed morphia frequently may be able to dispense with it entirely. But one difficulty presents itself: it is frequently impossible to prove with absolute certainty that there is complete transverse division of the cord, and in a case where there is any doubt it is clearly advisable to operate. When the slightest evidence of continuity of the cord exists an operation is imperative, and the earlier the operation is performed the better for the patient, care being taken to exclude from this rule cases of mere concussion.

Laminectomy being decided upon, the X rays will show the position of any metallic fragments, though, unfortunately, depressed portions of lamina may be quite invisible in the skiagrams, so that we must not trust them implicitly or invariably to supply the actual cause of pressure on the cord. It often happens that at the operation the surgeon finds that a portion of a lamina is obviously exerting pressure on the cord, when not a sign of its presence had been afforded by the X rays. An important question arises at this stage, shall the uninjured dura mater be opened? The answer must depend on whether compression of the cord can result from the pressure of a blood-clot within the theca. Some surgeons consider that it may, but Colonel SYMONDS holds the contrary view, and he bases his opinion on the fact that in the cases treated in the South African campaign no such cases were found, and that he has never met with the condition himself. While it can hardly be denied that it may occur, it must be rare. An opening of the dura mater adds, however, little to the danger of a laminectomy, and septic meningitis practically never follows it. When the lesion is situated in the cauda equina the conditions are different, for the nerves there

will unite after suture in the same manner as any peripheral nerve; therefore a damaged portion may be excised and the ends brought together with a great expectation that they will unite with a full restoration of function. This certainly cannot be done with the cord itself, though many attempts have been made. Even experiments on the lower animals to suture the spinal cord have all failed. The cord may certainly recover much of its lost function without operation, but no one can doubt that a timely removal of pressure must go far to assist the cord in its recovery.

We may sum up by saying: that in gunshot injuries to the spinal cord an early operation offers the best chance for the patient; that fear of the presence of sepsis need not deter the surgeon from operating; and that not until the surgeon has exposed the spinal dura mater can he speak with any certainty as to the mode in which pressure is being exerted on the cord. It may well be that in the future we shall be able to deal more actively with injuries to the cord, but at present all that the surgeon can do is to relieve pressure and to hope that the cord will be able to recover in part at least from the injury which it has sustained. Experience has shown that in a certain proportion of cases of injuries of the spinal cord much may be done, though in others all the surgical knowledge and skill which we now possess are insufficient to do any good. Workers in this branch of surgery feel that there are many points which can hardly yet be called settled, and Colonel SYMONDS has discussed them most illuminatingly in his lecture.

## Annotations.

"*Ne quid nimis.*"

### LESS BEER AND MORE BREAD.

No one can quarrel with the conclusion that to-day bread should claim greater respect than beer. The conservation of cereals for food purposes is of the utmost importance and it is absurd to contend seriously that beer forms, or has ever formed, an essential constituent of our food. Bread is a food and beer is a beverage, and these are quite different categories. Few people drink beer because it happens to contain a certain proportion of nutritives in the form of malt sugar, dextrin, and some proteins; it is appreciated as a pleasant, and, in the majority of cases, wholesome drink, and these qualities have made it the national beverage. But although beer does not contain a large amount of nutrient material, there is good reason for saying that in the healthy individual it favours the assimilation of food in a manner akin to such condimental substances as pepper, salt, and vinegar. Beer certainly contains, amongst other things, the vitamines in a remarkable amount, as might be expected having regard to the chemistry and physiology of its raw materials and the method of its production. There is, therefore, little question that beer increases assimilative power, thus adding to the nutrient value of the foods partaken with it. In spite of these considerations the increased output of bread at the expense of beer materials is clearly a sound policy when a shortage of food

supply is to be avoided. Bread and water in reasonable quantities will sustain life; the equivalent in beer would be an inconvenient bulk of material, and, besides, would introduce more alcohol than would be good for the consumer. Thus a pint of beer of moderate strength would, broadly, be equal in food value to 1½ ounces of bread; a pint of light beer would be worth about half this in nutritive value. So we may dismiss any suggestion that beer is a material food, for assuming, at a low estimate, that the daily consumption of bread is half a pound only, the equivalent of this, as regards nutritive value, would be 8 pints of ordinary beer, and a larger measure of light beer. This comparison renders the claims for beer as a direct and economic food material inadmissible, and shows how sound is the action of the Food Controller in further restricting the output of beer so as to husband the supply of grain for direct food purposes. The good sense of a similar restriction in regard to the output of spirits made from farinaceous products is obvious, though exception can be made in the case of wines which are made from the grape. The grape, unlike grain or the potato, is a perishable article, and its conversion into wine would not cause any interference with the supply of food. Brandy disappears automatically with the call upon wine for the use of the troops in France, and its rapidly advancing price will soon become prohibitive to purchase, in which case any restrictive order might well be superfluous.

#### THE PRESCRIBING OF COCAINE.

WE learn that it has been brought to the notice of the Home Secretary that the requirements of the Defence of the Realm Regulation 40B concerning prescriptions containing cocaine are not being fully carried out by all medical practitioners. A warning has therefore been issued from the Home Office stating that it is obligatory on every practitioner, when giving such a prescription, to date and sign it with his full name and address and qualifications; to mark it with the words "Not to be repeated"; and (except where the medicine to be supplied is a proprietary medicine, in which case it is sufficient to state the amount of the medicine) to specify the total amount of cocaine to be supplied. Failure to comply in any respect with these requirements is an offence against the Regulation which is punishable summarily, and pharmaceutical chemists are forbidden to dispense cocaine on any prescription which is not in compliance with the requirements.

#### AN AMERICAN OPINION ON BIRTH CONTROL.

Dr. T. D. Crothers, who read a paper recently before the Medico-Legal Society of New York upon the subject of birth control, that is to say, of the prevention of child-production by unsuitable parents, is an uncompromising advocate of State-exercised compulsion in such matters. The object sought is one which all will admit to be desirable, but whether the means necessary to attain it with anything approaching to certainty will ever commend themselves to the public in our own country is another matter. It is enough to say that appeals to potential parents of the undesirable class are not likely to produce any general results, and that it may be rash to prophesy what future generations will consider expedient. In the

United States, as in European countries, it is observed that the fewest births are found in the families best able to support and bring up children. On the other hand, in families where conditions of heredity and environment are most adverse the largest numbers of births are found. In these circumstances Dr. Crothers recommends the compulsory sterilisation of criminals, idiots, epileptics, inebrates, and drug-takers, the destruction at birth of abnormal or defective children, and he would "hold the parents responsible and make it the highest crime to attempt to give birth to defective children." The last-mentioned offence appears to be rather obscurely defined in the summary before us, but the intention is fairly clear. Dr. Crothers cites, as an illustration of the spirit in which he would legislate, an old Chinese custom, which consisted in fining the parents of an assassin as well as executing the criminal, the parents themselves being put to death if a second of their children committed a similar offence.

#### THE SERUM TREATMENT OF SPIROCHÆTOSIS.

AT the time of their discovery of the spirochæte of Weil's disease Professors Inada and Ido claim also to have found in the blood of convalescing guinea-pigs immune substances which dissolved and killed the spirochæte. Ido was shortly afterwards able to demonstrate a remarkably potent effect of the serum of immunised goats upon the disease in the guinea-pig. If injected before jaundice appeared the attack was in every case cut short. Salvarsan had, contrary to expectations, exerted very little effect on the disease in man, and the Japanese observers proceeded to carry out investigations on the value of serum treatment in patients, the results of which are set out in a paper signed by Inada, Ido, Hoki, Ito, and Wani in the *Correspondenz-Blatt für Schweizer Ärzte* of Jan. 20th. The serum first used was that of human convalescents, later that of horses ultimately immunised to tolerate an injection of 800 c.c. of a pure culture of spirochætes containing 30 organisms to the microscopic field (1/12 oil immersion, ocular 3). But serum of this extreme potency could not be obtained for the treatment of patients as it was not prepared until cases of the disease were no longer available. Thirty-five patients were treated, 23 in hospital and 12 in a coal-mine. At first 10 c.c. of serum were injected on each of three successive days, but this dose was soon found to be insufficient, and finally 60 c.c. were given within 24 hours in divided doses intravenously without any harm resulting from sudden lysis of the spirochætes. In 24 cases jaundice was present before serum treatment was begun. The authors employ five criteria to judge of the result of treatment: (1) The death-rate of 23 cases serum-treated in hospital was 17 per cent., compared with 31 per cent. in the cases treated without serum during the previous year; (2) with slight exception 40-60 c.c. of serum were sufficient to kill within 6 to 24 hours the spirochætes in the circulating blood, tested by injecting a sample into a guinea-pig; (3) immune bodies in the patient's blood reached their full development on the average two days earlier in serum-treated cases than in others; (4) in fatal serum-treated cases the spirochætes were less abundant than in untreated cases and showed distinct signs of degeneration; (5) no definite effect on fever, jaundice, or haemorrhagic tendency was noted in the serum-treated cases. The authors

make no comment on these results except to suggest that Weil's disease, although a spirochaetal infection, offers a suitable field for serum treatment, inasmuch as true relapse never occurs, immune bodies develop in the blood in the course of the disease, and this serum immunity, when it has developed, persists long after recovery, in one case up to eight years. Both their results and the proper reserve of their conclusions merit attention.

#### CLIMATE AND HEALTH.

IN the recent Gresham Lectures on Physic, which, in the absence of Colonel F. M. Sandwith, A.M.S., in Egypt, have been delivered by Dr. Harry Campbell, the lecturer chose as his subject the Influences of Climate on Health. He pointed out that each race and sub-race tends by natural selection to become adapted to the particular region of the earth which it has inhabited through numerous generations, so that, speaking broadly, the climate in which any given individual thrives best is that to which his ancestors have been long accustomed. Man has spread more widely over the earth than any other creature and is able to thrive under the most varied climatic conditions—tropical, Arctic, temperate, mountainous, marine, and the rest—but this, though true of the human race at large, is not true of the individual human. Although he exhibits greater climatic adaptability than any other animal, his power in this respect is nevertheless limited; the negro, for instance, cannot thrive in the Arctic zone any more than the Esquimo can in the tropical zone, the fact being that the various races of mankind—black, white, yellow, and their subdivisions—have by a long process of natural selection become adapted to their own special regions. If a race migrates far north or south of its native zone it tends to die out, and can only become adapted to the new zone by a process of gradual evolution. From this we are asked to believe that the fear entertained by some nations of a black or a yellow domination is groundless, since the various races are, from the nature of things, compelled to remain within definite confines. We must further conclude that in the gradual process of time definite types will evolve in Australia, New Zealand, and other of our colonies, as well as in the United States of America. This influence of climate in evolving racial types is of profound interest. The blonde race, as Dr. Woodruff has forcibly argued, had its origin in the cold, cloudy north-west region of Europe, where a plentiful supply of cutaneous pigment is not necessary in order to protect the body from the actinic rays of the sun, and where a white skin acts beneficially by favouring the retention of the body-heat, on the same principle that a bright teapot retains the heat longer than a black kettle. This fair race having evolved under the most rigorous conditions, of all races displays the most energetic disposition. It is, indeed, the dominating race of the world. Successive swarms of blondes have for thousands of years past migrated southwards and eastwards, and took a large part in founding the civilisations of Greece and Rome, as well as of Egypt and India. Owing, however, to their inability to survive in a latitude far south of their native zone they have gradually been eliminated and thus left no descendants. Dr.

Campbell adduced the remarkable fact, as showing the dominating influence of the blonde type, that all the Presidents of the United States of America have had blue eyes, and stated the same to be true of the leading generals in the present war—French, Haig, Joffre, Hindenburg, and Mackensen. The great Napoleon, though a Corsican, had grey eyes. Nothing better shows the influence of climate on racial type than the fact that in all countries the complexion darkens with diminution of latitude. Even after so short a period as 13 generations the inhabitants of the Southern States of America are darker than those of the Northern States. In process of time the blonde type will die out in the United States. We are apt to forget that the most northern of them are south of Penzance. Such considerations emphasise the truth that the climate of our ancestors is the one to which we are racially adapted—the one in which we are most likely to enjoy the best health. This principle applies not only to large sections of mankind but even, it may be, to small sections, such as the inhabitants of the various countries of the British Isles. Dr. J. S. Mackintosh has recently insisted upon this point,<sup>1</sup> urging that due regard should be paid to it in any scheme for settling soldiers on the land after the war.

#### HISTOLOGICAL CHANGES IN THE SPINAL CORD FOLLOWING BULLET WOUNDS.

Dr. Aubrey Mussen, assistant in psychiatry, Johns Hopkins Hospital, acting neuropathologist under the Medical Research Committee, London, has published in the October number of the *Review of Neurology and Psychiatry* the results of an investigation into the finer histological changes produced in the cord by direct injury or by concussion of the vertebral column. His material comprised bullet injuries of the brain, with secondary effects on the spinal cord; bullet wounds involving the cord directly; and bullets imbedded in the body of a vertebra without direct injury to the spinal medulla. In a case where the patient lived ten hours after a frontal lobe injury from a hand grenade, there was distinct evidence in certain areas of the spinal cord of bends, twists, and swellings on the axis-cylinders. In a second case, the duration of life after a transverse lesion of the cord at the first dorsal segment being 24 hours, axis-cylinders in the cord showed twists, kinks, and loop formations, and often short, sharp waves, as though from the shock of the concussion. Dr. Mussen has a series of four cases where death occurred 10, 24, 48, and 60 hours respectively after the injury, from an examination of which it is certain that marked degeneration has set in, even in the earliest. These are direct or traumatic degenerations, and are not comparable to what are usually termed secondary degenerations. It is rare to get the opportunity of examining such cases in civil life, and when they are seen, only ordinary secondary degenerations are found, as a rule. But in injuries due to bullet wounds the concussion caused by the impact of the bullet, which at 200 yards would strike a terrific blow in 1/50,000th of a second, produces a commotio the effects of which are transmitted through the dura to the spinal fluid, ligaments, pia mater, and septa into the cord substance, hence lacerations, haemorrhages, and injuries to the neurones, and this, too, in regions many segments removed

from the seat of the injury. Dr. Mussen quotes an interesting letter from the Shooting Editor of the *Field*, in regard to the striking force of the .303 Mark VII. service bullet, weighing 174 grains. At 200 yards its velocity is 2020 feet per second, and its striking energy 1010 foot pounds. Assuming that such a bullet striking the body at that distance is pulled up in three inches by the skin, muscles and spinal column, the resistance offered by the tissues is something like 4000 pounds. This may be regarded as the static pressure of the bullet acting against the tissues. The impact of such a force must produce tremendous disturbances, especially since its shock effects can be transmitted to the spinal fluid, where they set up a hydraulic force which acts radially. Dr. Mussen remarks it would be of value to examine the cord in cases of sudden death from concussion produced by the explosion of a shell without any direct injury whatever. It would appear not improbable that another form of concussion might produce similar disturbances to those so minutely detailed in this useful communication.

#### ROYAL BRITISH COLLEGE OF NURSING.

THE recent amalgamation of the College of Nursing (Limited) with the Royal British Nurses' Association (Incorporated) is a further stage in the public support accorded to the College. The proposal to found such a College was first publicly made by the Hon. Arthur Stanley, chairman of the Joint Red Cross War Committee, in the form of a letter sent to the heads of hospitals and nursing institutions, with the avowed object of organising the teaching and examining of candidates for the nursing profession. Guiltless in intention, the proposal did not, owing to its manner of presentation, meet with immediate approval by the Central Committee for the State Registration of Nurses, which has for many years past worked unremittingly to further Parliamentary action in the interests of the nursing profession, and with which were affiliated the principal nursing associations of Great Britain and Ireland. Towards the end of last year, however, a series of conferences was arranged between the College and the Central Committee, and, after a large measure of unity had been found, negotiations were finally broken off by the Central Committee owing to certain clauses in the proposed Nurses Registration Bill not being accepted by the College. But in the meantime the membership of the College steadily increased by the enrolment of individual members of nursing associations affiliated to the Central Committee, and, finally, the Scottish Nurses' Association threw in its lot definitely with the College of Nursing, whilst retaining the management of its own affairs by a Scottish Board. The affiliated society with the largest membership is the Royal British Nurses' Association, which has now amalgamated with the College. On the granting of the supplementary charter, for which application has been made, the College of Nursing will be wound up in favour of a new Royal British College of Nursing.

#### JUVENILE DELINQUENCY.<sup>1</sup>

JUVENILE lawlessness, it is stated in "The Child and the War,"<sup>1</sup> issued under the auspices of the Howard Association, has spread through the

<sup>1</sup> The Child and the War: being Notes on Juvenile Delinquency. By Cecil Leaon. Published for the Howard Association by P. S. King and Son, London. Price 1s. net.

country like a plague, and although exact statistics are not yet available, there is already sufficient evidence to show that, taking the large towns as a whole, an increase of over 50 per cent. in cases of larceny by quite young persons has occurred, while charges for assault, wilful damage, and gambling are much more numerous. The environment of the present-day child is abnormal. The lack of parental control owing to the exigencies of war, the darkened streets affording opportunities for lawlessness, the mental atmosphere coloured by martial passions: these are all factors inimical to the welfare of the child, and, as the pamphlet points out, punishment, whatever form it may take, affords no real remedy for the evil. The healthy child possesses an unbounded vitality which must have an outlet, and its deeply rooted instincts need guidance and diversion into proper channels. The Howard Association advises the appointment in every district of a children's joint committee composed of members of the local council and magistracy, with powers to co-opt ministers of religion and other social workers. The idea is an admirable one. The Association suggests, further, the enlargement of the sphere of the probation officer and the cooperation with him of carefully selected women of good education. Adequate play-centres are a necessity if the delinquency problem is to be dealt with in a practical manner, and we are glad to know that the Board of Education proposes to give grants for this purpose. Last summer the Board sanctioned the employment in agriculture of nearly 15,000 boys and girls of school age, roughly, half of them between 13 and 14 years old and the remainder between 11 and 13. Such an outlet for superabundant childish energy has much to commend it at the present time. Unfortunately it leaves untouched the long winter evenings, which are the chief difficulty.

Dr. Edward Coey Bigger, Medical Commissioner of the Local Government Board for Ireland, has been nominated by the King a member of the General Council of Medical Education and Registration of the United Kingdom for Ireland.

#### THE LANCET, VOL. II., 1916 : THE INDEX.

OWING to the continued shortage in the paper-supply the Index and Title-page to the volume of THE LANCET which was completed with the issue of Dec. 30th, 1916, have been printed separately, and copies have been supplied gratis to those subscribers who have, up to Feb. 1st, intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted, on application to the Manager, THE LANCET Office, 423, Strand, London, W.C. Such applications should be sent in at once.

THE Hawkmoor Sanatorium for the treatment of tuberculosis near Bovey Tracey, erected at a cost of £14,500 and containing 60 beds, has been formally opened by the Devon county council.

DUBLIN UNIVERSITY ELECTION.—The nomination of candidates for the Parliamentary representation of Dublin University took place on Tuesday last. As already announced, the candidates are Mr. A. W. Samuels, K.C., and Professor Sir Robert H. Woods, M.Ch. Polling began on Wednesday and will continue till next Monday afternoon.

## THE CONTROL OF VENEREAL DISEASES.

### *The City of Aberdeen Scheme.*

Dr. Matthew Hay, medical officer of health of the city of Aberdeen, has sent us the draft of a scheme which has been before his Public Health Committee. The scheme has been drawn up in consultation with the county medical officers of Aberdeen, Banff, and Kincardine, and representatives of the medical profession in Aberdeen and the three counties. The Royal Infirmary of Aberdeen is proposed as the treatment centre, without precluding the provision of facilities elsewhere later. Cases in the later stages are to be treated as heretofore in the ordinary wards, and the existing provision of special wards to be extended to about 20 beds. For the out-patient treatment of early and more infectious cases special clinics are proposed, or mixed clinics in association with cases of skin disease, to be held on at least two days and two evenings in the week for both sexes separately. The special medical staff is to include a surgeon and a physician, who will form part of the infirmary staff, the appointments to be provisional during the war. After the close of the war these special officers will be allowed to engage in consulting but not general practice. A junior medical assistant will assist the special staff in the venereal wards and clinics, and also be at the disposal of medical practitioners to advise them in home treatment. The bacteriological services required under the scheme are to be given in the laboratories attached to the infirmary under the general supervision of the chief pathologist. If the approval of the Local Government Board is obtained fees are to be offered to the medical practitioner for procuring blood for Wassermann test (5s) and samples of secretion (2s. 6d). The question of the payment of general practitioners for treatment of venereal diseases in private practice is to be held over at present. But nothing is understood to stand in the way of the practitioner being remunerated as usual by patients able and willing to pay for treatment, and in such cases laboratory tests will still be made gratis and possibly salvarsan supplied. Finally, the University is to be asked to take steps to ensure the practical instruction of all medical students in the diagnosis and treatment of venereal diseases.

### *The City of London Scheme: The Position of the General Practitioner.*

In his address last week to the British Hospitals Association on the treatment and control of venereal diseases, with special reference to the voluntary hospital, Dr. W. J. Howarth dwelt in some detail on the scheme for the City of London drawn up by himself as medical officer of health. As we have already stated, an existing hospital in Golden-lane is to be used as the treatment centre, beds being provided there for ordinary routine work. For cases requiring special treatment arrangements will be made for the use of beds at St. Bartholomew's Hospital. The clinic will be provided with waiting-rooms, consultation-room, dispensary, two wards, two operating or special treatment rooms, and a teaching and demonstration-room. Special laboratory work will be carried out under the direction of the hospital pathologist and routine clinical examinations at the centre itself. Residential accommodation for the staff is attached. The whole centre will be under the direct administration of the hospital authorities. The staff, in addition to the nurses and general helpers, will include a member of the honorary staff, who will be in charge, assisted by a whole-time non-resident officer and a resident medical officer who will divide his time between the work of the skin department and that devoted to the treatment of venereal diseases. Assistance by general practitioners is under consideration. Provision is being made for free bacteriological examination of morbid products, the free supply of salvarsan, and for educational and publicity work. The Corporation have suggested as payment a maximum sum of £1800 for the first year, exclusive of the cost of salvarsan or its substitutes. The capital expenditure necessary for the equipment and alterations, estimated at about £1000, will be borne by the Corporation. Dr. Howarth states that quite apart from the City scheme arrangements already have been made at St. Bartholomew's Hospital for putting into practice the early preventive treatment described in our leading article of Jan. 13th. The facilities are only used by soldiers.

Dr. Howarth went on to define the position of the general practitioner to the venereal schemes.

"I do not think," he said, "that hospitals are going to attract patients on a higher social scale for this special treatment than they do to-day for other treatment. Possibly, even some of those who attend for free treatment of other diseases, and who could pay their own doctor—there are such attend hospital out-patients' departments—will not seek free treatment for venereal infection. This section of the community will consult their own doctors, if they seek medical advice at all. I express a doubt here, because I fear that the quack, if allowed to flourish, will maintain his position as an active competitor. This should not be, and the hospitals, whilst accepting responsibility for imparting knowledge to practitioners, must assist him to obtain his rightful position by joining in the present agitation in favour of suppressing unqualified treatment and quack advertisements. The interest of the practitioners must be active and not passive. There is too much of the passive tendency in the latest introductions, in which treatment is undertaken at the instance of local authorities. This must inevitably result if special places are established with clinical responsibility limited to a public officer and inadequate encouragement given to the local practitioners. It is an undoubted necessity that medical practitioners shall be actively interested in all public medical work. Where hospitals exist evry opportunity should be taken to extend the sphere of usefulness. The establishment of new centres, unless circumstances require it, is a source of weakness, and coincidently with this increased activity the duty of the hospital to the public must not be lost sight of. This duty is closely associated with continuous educational facilities for the medical profession as a whole."

### *Deputation on Unqualified Practice.*

Lord Rhondda, President of the Local Government Board, received on Jan. 24th a deputation urging that unqualified practitioners should be prevented from undertaking the treatment of venereal diseases. The Royal College of Physicians of London, the British Medical Association, and the National Council for Combating Venereal Diseases were represented, as well as the associations of local authorities. The deputation was introduced by Sir Hamar Greenwood, M.P. The Lord Mayor of Birmingham, speaking on behalf of the Association of Municipal Corporations, said that public money should only be spent where there was prospect of the best results, and in order to protect the work of the local authorities quack advertisements should be suppressed and unqualified persons prevented from treating cases. Dr. Frederick Taylor, on behalf of the Royal College of Physicians, said that venereal diseases ought to be treated by those who knew how to do so. Mr. E. B. Turner, speaking as chairman of representative meetings of the British Medical Association, said that the Association had passed strong resolutions on the subject. The medical profession, in seeking to ensure efficient means of treating venereal diseases, was working for the general good of the community. Sir Malcolm Morris expressed the hope that a Bill suppressing quack treatment would be introduced. Lord Rhondda, in reply, said that his department fully realised the burning nature of the question of unqualified practice. He looked upon it as one of the most urgent and important questions to be dealt with in the near future. He had been greatly impressed with the complete agreement on this subject between local authorities and the medical profession, and assured the deputation that legislation would probably be brought in by one of the State departments—probably the Local Government Board—at an early date. Replying later to a vote of thanks, Lord Rhondda added that he was perfectly satisfied that the medical profession were actuated in this question by considerations of State policy and not by self-interest.

### *Sickness Benefit and the Friendly Societies.*

In its final report issued last week on Approved Society finance and administration in connexion with National Health Insurance the Departmental Committee recommends societies to alter their rules so as to enable them to pay benefits in sickness due to venereal diseases, basing its recommendation on the danger to the community of the venereal patient.

### *Supply of Salvarsan without Formalities.*

A recent Order issued under the Defence of the Realm Acts facilitates the distribution of salvarsan and its approved substitutes. During the war the Local Government Board may authorise any local authority or person to

buy and distribute "any drug, medicine, or medicinal preparation specially designed for the treatment of venereal diseases" without incurring any liability to proceedings "in respect of the importation, purchase, sale, distribution, or use thereof on the ground that any patent or other similar rights are infringed."

## Public Health.

### REPORTS OF SCHOOL MEDICAL OFFICERS.

*Bristol* ranks sixth among the cities of England and Wales in regard to population, after the metropolis, and has a school roll of 59,372. The report of 1915 is furnished by Dr. Madeleine Baker, in the absence of Dr. R. A. Askins on military service. The number of children examined as entrants, leavers, and in the intermediate group was 15,088. The state of nutrition was found to be "normal" in 83·2, and excellent in 13·3 per cent., only 3·46 per cent. being considered to be below normal, and of these only 0·17 to be actually badly nourished. The cleanliness of the children was also very satisfactory, 98·8 per cent. being returned as clean, and only 0·05 per cent. being found to have body vermin. The children's eyesight was found to be perfect in each eye in 47·5 per cent. of those examined, while an additional 40 per cent. possessed at least 6/9 of normal vision in either right or left eye. Organic heart disease was diagnosed in 1·31 per cent., being considerably more prevalent among girls (2·17 per cent.) than boys (1·04 per cent.) at the leaving age. Tuberculosis of the lungs was found in 0·12 and suspected in 0·55 per cent. of the children; other forms of the disease (glandular and articular) were found in 0·20 per cent. Two school clinics were opened in June, 1915, one in New-street and the other in Bedminster-parade. These clinics are used for the two purposes of inspection and treatment. Inspection clinics are also held at New-street special school and at the Bedminster school for mothers. The treatment clinics deal with children that would otherwise obtain no treatment, especially in regard to affections of the skin, eye and ear. Notifiable infectious diseases were much less prevalent during 1915 than in the previous year, 795 cases as compared with 1745 in 1914, scarlet fever (553 cases) and diphtheria (228) being the most important. Non-notifiable infections were, on the other hand, more prevalent, measles being the chief. No school closure for epidemic disease was required, except for a fortnight in a single school. The chief cause of death among school children was tuberculous disease (46 fatal cases), either of the lungs, the meninges, or in other situations. Pneumonia caused 26 deaths, organic heart disease 18, diphtheria and croup 14, and meningitis (non-tuberculous) 14. Two open-air schools have been at work throughout the year, the larger one at Knowle, with an average attendance of 69, and a smaller one at Barton Hill; anaemia, malnutrition and general delicacy, and tuberculosis contacts have been the cases chiefly treated, and the effects have been most beneficial. The children take a keen interest in gardening, have the advantage of walks in the country, and are ensured a midday rest, as well as the use of a shower-bath.

At *Cardiff* the average school attendance during 1915 was 27,982; the number of children examined in the entrant and leaver groups was 5936. The report is furnished by Dr. Edward Walford, medical officer of health for the city and port. The state of nutrition was found to be normal in 73·1 and excellent in 13·9 per cent.; in 12·7 per cent. it was below normal, and among these in 1·3 per cent. it was classed as distinctly bad. The body cleanliness was satisfactory in 94·7 per cent.; in 2·3 per cent. vermin were found to be present. The eyesight was examined in 2918 children of the "leaver" age (12 to 14 years); it was found to be perfect in each eye in 52·9 per cent., and an additional 16 per cent. possessed 6/6 in either right or left eye. Organic disease of the heart was found to be present in 0·72 per cent.; amongst boys the incidence was 0·91 and amongst girls it was 0·52 per cent. Tuberculosis of the lungs was found in 0·06 and suspected in 0·30 per cent., and in a further 0·2 per cent. non-pulmonary tuberculosis was diagnosed. A school clinic has been in operation since 1913 in the basement of the City Hall, where defects of

the ear, nose, and throat are treated, and examinations made for defective vision.

In Mr. Joseph Beard's report on *Carlisle* schools special attention is drawn to the erection of a new infants' school at Newtown, which "marks a great advance in the hygienic construction of elementary schools." Classroom accommodation for 400 is provided on a basis of nine square feet per head, with verandahs for teaching and a central play-room in addition. All class-rooms have windows on two sides at least carried up to the ceiling; the corridor windows are removable, so that in summer the corridors may be entirely open to the air. Heating is on the low-pressure hot-water system, the pipes being placed on the north side of the class-rooms and at a high level so as to obviate down draughts. The medical examination has included 2675 entrants, leavers, and 8-year-old children. Their nutrition was found to be normal in 69·3 per cent. and excellent in 12·4 per cent.; in 18·2 per cent. it was below normal, but in only 0·1 per cent. was it considered to be actually bad. Cleanliness of the body was satisfactory in 86·8 per cent., and only 0·6 per cent. were considered to be actually dirty, though 1·3 per cent. in addition were verminous and 3·0 per cent. flea-bitten. Perfect vision was possessed by 68·8 per cent. of the children of "leaver" age. Of the children in the leaver and intermediate groups 97 per cent. had perfect hearing, as shown by the whisper at 20 feet. Organic heart disease was found in 1·3 per cent. of the total number of children, being nearly twice as frequent among boys as among girls. This disparity resulted entirely from the preponderance in boy entrants (503), in 11 of whom organic heart disease was diagnosed, while in a nearly equal number of girls (483) only one such case was found. Tuberculosis of the lungs was found in 1·3 and suspected in 8·4 per cent.; other forms of tubercle were diagnosed in an additional 1 per cent.

Dr. W. G. Willoughby, in presenting the report to the education authority of *Eastbourne*, states that Dr. Norah Smith has been practically school medical officer during the year 1915 on account of his own service in the Army, and draws attention to the fact that there is again a decrease in the number of children attending the elementary schools, due to the rapidly diminishing birth-rate; in five years this decrease has amounted to 153. The total number of children inspected at the routine age-periods (entrants, intermediates, and leavers) was 1902. Of these, 25·5 per cent. were found to be in an excellent condition as regards nutrition, 52·3 were normal, and 22·2 below normal, 8·3 being actually badly nourished. As regards cleanliness, 89·3 are returned as clean, only 1·5 per cent. being considered to be dirty; in addition pediculosis was found in 1·2 per cent., and 8·1 per cent. are returned as "P.I." The vision was perfect in each eye in 80·9 per cent. of the leavers and intermediate group. Organic disease of the heart was diagnosed in 0·9 per cent., being much more prevalent amongst girls (1·31) than boys (0·51 per cent.). Tuberculosis of the lungs was found in 0·1 and suspected in 0·2 per cent. of the children examined. Non-pulmonary tuberculosis (glandular) was found in an additional 0·3 per cent. A clinic has been established for minor ailments (chiefly ear, eye, and skin defects), where the children attend each whole school day at 10 A.M. It had been found that their attendance at intervals and the issue of ointment, lotion, &c., for use at home was unsatisfactory, as the parents did not follow the instructions given.

The report on school medical inspection at *Newark* for 1915 is a short one, as Dr. S. Nicol Galbraith was appointed only at the beginning of November, there having been an interim without a school medical officer since May 31st, when Dr. E. A. B. Poole ceased to act. The number of children examined at the routine ages was 510; of these, 30 per cent. were "excellent" as regards nutrition, 14·5 were regarded as below normal, only 0·8 per cent. (4 children) as actually badly nourished, and the rest were classed as normal. Cleanliness was quite satisfactory in 97·5 per cent. Vision was perfect in each eye in 81·5 per cent. of the leavers and children of intermediate age; in only 8·6 per cent. was visual acuity less than 6/9 of the normal. Organic heart disease was diagnosed in 1·17 per cent. (4 girls and 2 boys), and tuberculosis (glandular) was diagnosed in 2 children and suspected (pulmonary) in 5 others.

In the report on school hygiene at *Warrington* Dr. G. W. N. Joseph draws attention to the fact (perhaps not always fully

realised) that "whatever the necessity for carrying on the work of the School Medical Service was in the days before the war, the present abnormal conditions greatly intensify it.....It is more than ever essential that a generation of healthy children should be growing up." This is seen on examining the statistics of the causes for rejection of recruits, many of the defects being preventable or remediable if taken in time. The total number of children examined in the code groups was 3786: an almost equal number (3655) were inspected at the school clinic, being "special" cases, chiefly of impetigo, ringworm, pediculosis, and conjunctivitis and blepharitis. Of the code-group children the nutrition was considered to be above normal in 7·6, and normal in 83·7 per cent., only 8·6 per cent. being below normal and 0·2 per cent. markedly defective. Cleanliness both of the body and head was satisfactory in 99·8 per cent. In the intermediate and leaver groups 33·7 per cent. had perfect vision, and 31·5 per cent. had V. = 6/9 in each eye. Children able to read 6/12 are not dealt with unless there are other symptoms of visual defect; if only 6/18 can be read, the parents are asked to consult their doctor, but the matter is not pressed further; if there is any difficulty in reading 6/18 the parents are pressed, as far as it is possible, to obtain treatment. This procedure is more indulgent to the shortsighted than the usual practice. Organic disease of the heart was found in only 6 children (0·1 per cent.), 5 of whom were girls. Tuberculosis of the lungs was diagnosed in only one child and suspected in another; other forms of the disease (joints, glands, &c.) were found in five children. The work of the treatment clinic has increased enormously, the number of children dealt with having been nearly double, and the number of attendances more than double, the corresponding figures for 1914. Pediculosis of the scalp does not now receive treatment at the clinic. This was found to encourage laziness in the parent, to take up too much time, and to be a bad example to the other children. The proper procedure is explained to the parent by the school nurse (vinegar and water and a fine-tooth comb), and if rapid improvement does not follow it is advised that the hair be cut short. The great cause of failure is the use of too cheap, and therefore too coarse, a comb. Dr. Joseph notes that there is still a prevalent belief that "nits in the hair are a sign of good health in the child."

In the city of York the total number of children in the entrant and leaver groups inspected amounted to 1586; none of the "intermediate" age were examined. The nutrition was found to be normal in 73·5 and excellent in 14·8 per cent.; 11·7 per cent. were below normal, but none were actually badly nourished. Cleanliness of the body was satisfactory in 89·5 per cent., the remaining 10·5 being dirty, but in only 0·3 per cent. were pediculi found. The vision (of the elder children) was perfect in each eye in 46·9 per cent.; in 35·3 per cent. there was "less than 6/6, but not less than 6/9 in one or both eyes"; (presumably less than 6/6 in one or both, but not less than 6/9 in each eye); in 17·8 per cent. there was less than 6/9 "in one or both eyes." Perfect hearing was possessed by 97·8 per cent. of the children. Organic heart disease was found in 20 children (1·2 per cent.), of whom 6 were boys and 14 were girls. Tuberculosis of the lungs was not diagnosed in a single instance, and in only three children was it suspected; non-pulmonary tuberculosis was found in two children only—these are the figures given in Table II. referring to the age-group children examined. There were, however, 53 cases of tuberculosis notified during the year among children of from 5 to 15 years of age, 20 being pulmonary and 33 glandular, articular, &c.; this equals 0·45 per cent. of the school population. Dr. E. M. Smith's report is followed by a valuable study of the condition of the teeth in 10,000 York children by Mr. T. E. Constant, dental surgeon to the York clinic.

#### URBAN VITAL STATISTICS.

(Week ended Jan. 27th, 1917.)

**English and Welsh Towns.**—In the 96 English and Welsh towns, with an aggregate population estimated at nearly 18,000,000 persons, the annual rate of mortality during the week was equal to 17·0, against rates steadily declining from 23·7 to 16·2 per 1000 in the five preceding weeks. In London, with a population of more than 4,000,000, the death-rate was 18·4, or 1·9 per 1000 above that in the previous week; while among the remaining towns it ranged from 6·0 in Enfield, 8·1 in Acton, and 8·7 in Haling, to 24·3 in St. Helens, 26·0 in Ipswich, and 28·2 in Bournemouth. The principal epidemic diseases caused 193 deaths, corresponding to an annual rate of 0·6 per 1000, and included 70 from measles, 53 from infantile diarrhoea, 38 from diphtheria, 18 from

whooping-cough, 8 from scarlet fever, and 6 from enteric fever. The deaths from measles were slightly in excess of the average in the three preceding weeks, and caused a death-rate of 1·5 in East Ham and of 3·7 in Wimbleton. The 81 cases of scarlet fever under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 1 less, and the 1390 cases of diphtheria were 6 less than at the end of the previous week. Of the 5636 deaths from all causes in the 96 towns, 230 resulted from violence; the causes of 62 of the total deaths were uncertified, of which 10 were registered in Birmingham, 10 in Liverpool, and 5 in South Shields, but only 1 in London.

**Scotch Towns.**—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual death-rate was equal to 16·9, against rates declining from 19·6 to 17·6 per 1000 in the five preceding weeks. The 356 deaths registered in Glasgow corresponded to an annual rate of 16·6, were equal to the number recorded in the previous week, and included 6 from whooping-cough, 5 each from measles and diphtheria, and 1 each from scarlet fever and infantile diarrhoea. In Edinburgh the 103 deaths were equal to an annual rate of 16·2 per 1000, and included a fatal case of whooping-cough and 1 of diphtheria.

**Irish Towns.**—The 174 deaths in Dublin were equal to an annual rate of 22·7, or 1·7 per 1000 below that recorded in the previous week, and included 3 each from measles and infantile diarrhoea and 1 each from whooping-cough and diphtheria. The causes of 8 of the total deaths were uncertified. In Belfast 189 deaths were registered during the week, and corresponded to an annual rate of 22·4, or 2·9 per 1000 above the rate recorded in the previous week; 3 deaths were referred to measles, 3 to infantile diarrhoea, and 1 to whooping-cough.

#### THE SERVICES.

##### ROYAL NAVAL MEDICAL SERVICE.

To be temporary Surgeons: E. S. Orme, G. Hoffmeister, A. F. Grimby.

##### ARMY MEDICAL SERVICE.

Lieutenant-Colonels to be acting Colonels whilst employed as Assistant Directors of Medical Services of a Division: G. W. Tate, F. E. Gunter.

##### ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. E. Brodribb is placed on the half-pay list on account of ill-health.

Majors (acting Lieutenant-Colonels) relinquishing their acting rank on reposing: W. J. P. Adye-Curran, A. S. Arthur.

Major D. O. Hyde, D.S.O., to be acting Lieutenant-Colonel whilst in command of Field Ambulance.

Major T. P. Bradley, Canadian A.M.C. (Canadian Militia), to be temporary Major.

To be temporary Captains: F. H. Knaggs (whilst employed at the Huddersfield War Hospital), Temp. Lieut. E. P. Evans, J. L. Aymard, P. S. Blaker (late Capt. I.M.S.) H. Dodgson, L. M. Scott, C. R. Skyrme (late Surg.-Capt. R.G.A. (Vol.)).

Captains, from R.A.M.C. Special Reserve, to be Lieutenants, and granted the rank of temporary Captain: W. L. E. Reynolds, H. R. Sheppard.

To be temporary Lieutenants: D. N. Knox, T. Y. Finlay, J. H. Kay, J. C. Henderson, E. Miskin, M. R. Lawrence, Temp. Hon. Capt. H. Deardon, J. Dunton, C. C. Gibson, B. H. Woodyatt, T. J. Taunton, A. E. Woodall, A. Y. Hutchinson, J. Gardner, E. O'Reilly, T. E. Regan, J. D. Laird, T. Burrell, W. E. Barrett, D. A. H. Moses, A. C. Parsons, F. B. Elwood, J. G. Heath, J. R. O'Brien, R. L. Rea, W. F. H. Ives, A. P. Thom, E. C. B. Ibstock, J. W. Lindsay, J. Hogg, J. B. Howell, J. S. Doyle, R. L. Jones, R. Roberts, A. M. Crawford, T. J. McDonald, W. T. Hardie, T. H. Campbell, J. F. Wood, F. C. Stewart, J. Harper, R. E. Sedgwick, G. R. New, N. Flower, R. G. Cunningham, W. M. McFarlane, A. F. W. Millar, A. G. Holmes, W. A. Murray.

To be temporary Honorary Lieutenant: N. Sherrard.

Officers relinquishing their commissions: Temp. Major P. MacGregor (on account of ill-health), Temp. Hon. Major T. C. L. Jones (having ceased to be employed with No. 6 British Red Cross (Liverpool Merchants' Mobile) Hospital), Temp. Capts. A. H. Lyster, C. H. Shearman, S. H. Ormond, O. H. Edwards, J. E. Stacey (on account of ill-health), Temp. Lieuts. W. Thomson (on account of ill-health), H. A. Hutt, P. W. Barker, R. T. Jupp (on account of ill-health).

##### SPECIAL RESERVE OF OFFICERS.

Capt. (temp. Major) R. M. Beath relinquishes his temporary rank on ceasing to command Troops on a Hospital Ship.

To be Captains: W. S. Dawson, G. Perkins, J. N. L. Blamey, R. L. Newell.

To be Lieutenants: W. Garde-Browne, E. Hollott Creed (from University of London Contingent, O.T.C.).

##### TERRITORIAL FORCE.

To be Captains: Capt. A. Rodger (from a Mounted Brigade Field Ambulance), Capt. H. E. S. Richards (from Attached to Units other than Medical Units), Lieut. E. B. C. Mayrs, Lieut. W. F. Lanchester, Lieut. T. Higson, Lieut. A. Iredale.

To be Lieutenant: J. D. Davidson.

##### TERRITORIAL FORCE RESERVE.

To be Captain: Capt. F. G. Bennett, from a Field Ambulance.

**HART HOUSE V.A.D. HOSPITAL, BURNHAM, SOMERSET.**—A new wing and other additions have been added to this hospital and the accommodation increased by 50 beds. The institution now contains 120 beds.

**HOSPITAL SUNDAY AT PLYMOUTH.**—The South Devon and East Cornwall Hospital has received £562 as the result of the observance of Oct. 2nd, 1916, as Hospital Sunday at Plymouth.

## Correspondence.

*"Audi alteram partem."*

### THE PHENOMENA OF ANAPHYLAXIS.

*To the Editor of THE LANCET.*

SIR.—In connexion with Captain S. Wyard's paper in your issue of Jan. 20th, and the references to the same subject in your leading article, the following cases seem worth recording. They appear hard to reconcile with many of our present ideas concerning the mechanism of anaphylaxis, especially as regards the minimal toxicogenic dose and the desensitising effect of subminimal doses of antigen, recorded by Besredka, and advocated by him as affording efficient protection when administering antisera to patients suspected of previous sensitisation.

For certain reasons, which have no bearing on the point in question, the effect was tried of administering repeated small doses of antistreptococcal serum in a series of cases of streptococcal infections of varying acuteness. In some few cases an autogenous vaccine was administered concurrently with the serum. In the majority of these latter cases serum and vaccine were administered at the same time, sometimes separately and at different sites, in some cases together. When given together the serum and vaccine were mixed in the syringe immediately before injection. In all, some 28 cases were treated on these lines, and of these four developed acute anaphylactic symptoms. In one case two separate attacks were precipitated.

The essential details are as follows:—

CASE 1.—Severe streptococcal infection, originating in a traumatic injury to the wrist, with subsequent metastatic abscesses in the leg.

#### *Injections of Serum and Vaccine.*

	Antistrepto-coccal serum.	Antistrepto-coccal serum	Vaccine.
9/3/16 A.M. ...	2 c.c.	21 3/16 ... 2 c.c. ...	—
P.M. ...	2 c.c.	22 3/16 ... 2 c.c. ...	—
10/3/16 A.M. ...	2 c.c.	23 3/16 ... 2 c.c. ...	+ 10 mil. strepto-
P.M. ...	1 1/2 c.c.	25 3/14 ... 2 c.c. ...	+ 20 mil. occcl.
11/3/16 ...	2 c.c.	27 3/16 ... 0 25 c.c. ...	+ 25 mil. "
12/3/16 ...	2 c.c.	29 4/16 ... 0 2 c.c. ...	+ 25 mil. "
14/3/16 ...	2 c.c.	31 3/16 ... 0 5 c.c. ...	+ 40 mil. "
15/3/16 ...	2 c.c.	3 4/16 ... 0 5 c.c. ...	+ 50 mil. "
16/3/16 ...	2 c.c.	5 4/16 ... 0 5 c.c. ...	+ 100 mil. "
17/3/16 ...	1 c.c.	7 4/16 ... 0 6 c.c. ...	+ 200 mil. "
20/3/16 ...	2 c.c.	10 4/16 ... 1 5 c.c. ...	+ 200 mil. "

(Immediate anaphylaxis.)

In addition to these injections of serum the wound in the hand, and later the two small cavities in the leg, were dressed daily with diluted antistreptococcal serum (1/10 in normal saline), about 10 c.c. of the saline dilution being used at each dressing. On 14/3/16, and on most succeeding days 1 to 2 c.c. of pure serum was applied to the wound before the fresh dressing was put on. On no occasion were more than 6 c.c. of serum given in one day, including the actual injection and the amount used as a dressing for the wounds, and on the great majority of days the total amount varied between 2 and 4 c.c. The majority of the injections, including that which was followed by the anaphylactic attack, were given subcutaneously; a few were administered intramuscularly, none intravenously. No history could be obtained of any previous injection of serum.

CASE 2.—Streptococcal infection of wounds of leg.

#### *Injections of Serum.*

	Antistrepto-coccal serum.	Antistrepto-coccal serum.
18/7/16 ...	... 2 c.c.	22 7/16 ... ... ... 2 c.c.
19/7/16 ...	... 2 c.c.	22 7/16 ... ... ... 2 c.c.
21/7/16 ...	... 2 c.c.	28 7/16 ... ... ... 1 c.c.

(Immediate anaphylaxis.)

There were two small surface wounds and one long superficial sinus, open at both ends. These were irrigated daily with a 1/10 dilution of serum in saline, about 10 c.c. of the fluid being used on each occasion. All the serum injections were given intramuscularly in the immediate neighbourhood of one of the wounds. The infection in this case originated in a gunshot wound, and there was a probable injection of antitetanic serum about the end of the first week of April, 1916.

CASE 3.—Streptococcal infection of gunshot wound of buttock.

#### *Injections of Serum.*

	Antistrepto-coccal serum.	Antistrepto-coccal serum.
27/7/16 ...	... 2 5 c.c.	31/7/16 ... ... ... 2 5 c.c.
28/7/16 ...	... 2 c.c.	(Immediate anaphylaxis.)

The injections were given intramuscularly in the immediate neighbourhood of the wound. From 17/7/16 to

31/7/16 the wound cavity, which was at first large but rapidly decreased in size, was washed out with 10 c.c. of a 1/10 dilution of serum, as in the above cases. On 18/7/16, 10 c.c. of undiluted serum were injected into the wound cavity, but very little was retained in it, the greater part returning at once. This patient was wounded on July 1st, and received an injection of antitetanic serum before being evacuated to England.

CASE 4.—This was an acute streptococcal infection of the hand and arm, following trauma. The full notes of this case are not available at the present moment, but it was essentially similar to Case 1, with one important exception. Within a few days of admission the patient received three injections, each of 10 c.c., of antistreptococcal serum; these were without effect. He was then treated for three weeks with a streptococcal vaccine, also without effect. Small daily injections of serum were then commenced, combined with intermittent irrigation of the wound with diluted serum as above, and an immediate beneficial result was observed. After about 14 days of this treatment he suddenly had a sharp anaphylactic reaction following the injection of 2 c.c. of serum. This was the first case in which such a reaction occurred, and as it was thought that the patient had probably been desensitised, the injections were continued. About 14 days later another similar reaction occurred and no further serum injections were given. 2 c.c. was the largest amount administered at any one injection, and on several occasions 1 c.c. only was given. The injections were given subcutaneously and intramuscularly.

The symptoms were strikingly similar in all four cases. They started immediately after the injections had been given, in one case before the needle had been withdrawn, and in every case within a few minutes. Difficult and laboured respiration was a marked feature in each case. Marked cyanosis was present in two cases, while in the other two this was replaced by intense congestion and redness of the face, followed by profuse perspiration, which developed rather later in the two cases which showed cyanosis. In all cases pain was complained of: in three instances localised in the back, or back and side, in one in the abdomen. Each patient complained of a feeling of acute distress which he was quite unable to describe. In two of the cases, in which there was only a slight irregularity of temperature at the time of the attack, a slight pyrexial reaction followed, the temperature rising to about 100° F. on the same evening and then rapidly subsiding. The other two cases were suffering from definite pyrexia ranging from 99° to 102° at the time when the anaphylactic reaction occurred. Of these, Case 4 on each occasion showed only a slight exacerbation of fever, while with Case 1 the temperature rose the same night to 105·2, but then rapidly subsided. In each case the acute symptoms lasted for 5 to 15 minutes, but with one exception there was definite discomfort and malaise lasting for some hours. All four patients had completely recovered from the attack by the following morning, and they all subsequently made a complete recovery from their infections. No acute local manifestation occurred with these attacks, but one of the four cases and several of the other 24 treated on these lines exhibited transitory joint pains and urticarial rashes during the course of the infection.

It would seem difficult to offer any satisfactory explanation of these facts. Case 1 had apparently never received a previous and possibly sensitising dose of serum. Of the others, Cases 2 and 3 had received at most a few c.c. of antitetanic serum on one occasion. Case 4 alone had received a previous dose of any size. In this connexion it may be recalled that Holubot, dealing with bacterial anaphylaxis, demonstrated that sensitisation was more surely attained by repeated small doses of antigen than by a single large dose. The very small doses which actually gave rise to the anaphylactic attack are remarkable. The conclusion can, I think, hardly be avoided that we are dealing with a cumulative effect, an idea which is rendered more probable by our knowledge of the persistence of an antigen in the tissues after injection. Adopting this hypothesis, it might be supposed that a delicate state of equilibrium had been established between the antigen and antibody already in the tissues, and that the sudden addition of even a minute excess of the former sufficed to destroy this balance and precipitate the reaction which leads to anaphylactic shock. Such a suggestion is, of course, entirely lacking in satisfactory experimental support and presents certain obvious difficulties, but it is hard to find any explanation which will cover the facts without running contrary to many of the current theories.

The important practical point is that it would seem quite impossible to reconcile these cases with a trust in the

efficient production of desensitisation by a small initial dose of serum. In this connexion, if I recollect aright, Professor Andrewes in a paper on Cerebro-Spinal Meningitis, communicated last year to the Pathological Section of the Royal Society of Medicine, noted that in one case in which an attempt was made to desensitise a patient by a small preliminary injection of antimentingococcal serum, acute anaphylaxis resulted when the subsequent therapeutic dose was administered.—I am, Sir, yours faithfully,

W. W. C. TOPLEY,  
Bacteriological Department, Charing Cross Hospital,  
Jan. 20th, 1917.

To the Editor of THE LANCET.

SIR,—In the papers referring to anaphylaxis which have lately been published, it is a pity that most of the results given in them are in so vague and indefinite a form. Perhaps it is yet too early to expect much else. One would like to see numerical records of the total number of serum-treated cases seen by each observer, the number of cases in which anaphylaxis occurred, the amount of serum, the mode of administration, and the number of doses given. Also records of the severity of the anaphylactic attack, the time of onset, and the duration and the treatment adopted. Only thus will it be possible later to make trustworthy deductions. This is evident because in a few instances where definite figures are given they are obviously inaccurate. For example, in Captain S. Wyard's paper in THE LANCET of Jan. 20th it is stated that about 4-5 c.c. of serum are required to produce an anaphylactic attack in a sensitised guinea pig, and that "antigen administered by the mouth or rectum never produces anaphylactic shock," whereas the truth is that as many minimis given subcutaneously will often suffice in the guinea-pig, and in man I have seen and described a case in which 0.5 c.c. given by the mouth produced slight symptoms on two occasions in a man who had previously nearly died of anaphylaxis. Again, there may be something special about antitetanic serum to justify the assertion of the Committee of the War Office (quoted by Sir D. Bruce) that the danger of anaphylactic shock is negligible with 3 c.c. of horse serum after a preceding injection; but one would very much like to know whether there have not been any anaphylactic accidents as a result, not to mention fatalities. Of course, even if there have been, it does not follow that the risk is not justifiable: but the risk should not be concealed or ignored.

I am, Sir, yours faithfully,  
A. S. LEYTON.  
University of Leeds, Jan. 29th, 1917.

DEFINITION OF ACUTE ALCOHOLISM.

To the Editor of THE LANCET.

SIR,—From Dr. Chalmers Watson's letter in your issue of Jan. 27th it is apparently to be inferred that the records of the Edinburgh Royal Infirmary do not enable a distinction to be made between cases of delirium tremens and other less definite alcoholic conditions. This is unfortunate, and must tend, I fear, to make Dr. Watson's statistics less impressive than they might otherwise be. For it is obvious that an increase in the number of cases of delirium tremens would have an evidential value which cannot possibly attach to an increase in the number of cases of "acute alcoholism"—a category of vague and elastic limits which may quite probably include patients who were merely so "drunk and incapable" that an unusually sympathetic or inexperienced policeman would prefer to take them to the hospital rather than to the cells. And in this connexion it may be recalled that these cases, as Dr. Watson tells us, were "nearly all brought in by the police," and, no doubt, the Edinburgh police, like the police of other towns, have been freely diluted with special constables during the past year. Under these circumstances, it must remain a matter of some uncertainty by what precise criteria we are to distinguish the cases of "acute alcoholism" treated in the Royal Infirmary from the cases of "acute alcoholism" treated in the Edinburgh police stations. No such uncertainty would affect the value of statistics of delirium tremens, and if Dr. Watson were able to give figures showing that the incidence of that disease amongst women had really risen during the last year, the "curious paradox" of which he speaks would undoubtedly merit attention. And this all the more because no parallel for it is apparently to be found

anywhere in the country. In all the areas for which statistics of this kind have been published it has been the invariable rule that the decrease in arrests for drunkenness during the last 12 months has been associated with a decrease in the number of cases of delirium tremens treated in Poor-law institutions and in prisons. Nor is this observation limited to England; thus in Glasgow the number of patients treated for delirium tremens in the Eastern District Hospital and in the Govan Poorhouse during the period from mid-August, 1914, to mid-August, 1915, was 105—84 males and 21 females; while in the following 12 months, i.e., subsequent to the restriction of public-house hours under the Orders of the Central Control Board, the number fell to 70—59 men and 11 women.

Dr. Watson adds that he attaches little importance to the differentiation of delirium tremens, which he regards as "merely an incident in the development of *some* cases of acute alcoholism." This seems a rather surprising statement; at all events, I do not know of a single authoritative writer on alcoholism who does not accept the view that delirium tremens is a disease arising always on a basis of *chronic* alcoholism, and further, that it occupies a quite special and distinct position amongst the alcoholic psychoses. And this is most assuredly the teaching of general clinical experience. It is, in fact, by reason of its clear relation to the chronic intoxication and its comparatively definite and unequivocal clinical characteristics, that delirium tremens is so useful for statistical purposes, especially as an index of forms of intemperance which do not find expression in public drunkenness. Thus, for example, the increase of delirium tremens under the régime of prohibition in Russia is one of the most important evidences of the development of secret drinking and of the use of dangerous substitutes, such as denatured spirit, which has followed the adoption of that extreme policy.—I am, Sir, yours faithfully,

W. C. SULLIVAN.

London, Jan. 30th, 1917.

To the Editor of THE LANCET.

SIR,—I have read with great interest Dr. Edmund Cawley's address on the above subject published in your issue of Jan. 13th. Most of it might well have been delivered by an ardent advocate of a State Medical Service. He sees so clearly how inevitably the trend of things is towards the State assuming more and more responsibility for the health of its citizens, young and old, and he points out so well the defects of the present half-and-half system.

Though he cannot refrain from expressing his dislike of departmental officials, to whom he asserts, I think unjustly, that the interests of the profession are only of minor importance, he admits that there is no doubt that there has been an immense improvement in the control and prevention of diseases by the medical department of the Local Government Board and that good work has been carried out in its laboratories. He further admits that another set of departmental officials—the school medical officers—have done good work in securing efficient treatment for hundreds of children who would otherwise have been neglected. He might have gone further and admitted the excellent work of many other medical departmental officials. However, the point I wish to raise is whether the benefits Dr. Cawley admits to have taken place would have occurred if public health and medical inspection of school children had been left to private enterprise? The answer is obvious. Further, does the incidence of preventable diseases, the present high infant mortality-rate, and the percentage of children arriving at school age in some way physically or mentally defective (1 in 6), suggest that the present system of doctoring by private enterprise is satisfactory in its results? Surely it shows that however willing and capable individual doctors may be, the system is not one which can cope with the necessary work. If State interference and departmental officials have done much to control and prevent disease as admitted, is not the cure for these evils a still bigger dose of the same remedy?

There are many other points in the address on which I should have liked to comment, but I must not trespass further on your space. However, may I say in conclusion that I heartily agree with Dr. Cawley that it is incumbent on every member of the profession to watch and direct the current of

events. That current is flowing slowly, steadily, and unalterably towards a State Medical Service, and its strength has been intensified by the war, which has brought so prominently before the nation the importance of health and physical fitness and the urgent necessity for the preservation of child life. Let us so direct the current that, when a State Medical Service does come, it shall be one to which it will be both a pleasure and an honour to belong.

I am, Sir, yours faithfully,  
London, W., Jan. 26th, 1917. CHARLES A. PARKER.

### SPIROCHÆTAL JAUNDICE (SO-CALLED WEIL'S DISEASE).

To the Editor of THE LANCET.

SIR.—The admirable article, published in THE LANCET of Jan. 27th, by Captain A. Stokes, Captain J. A. Ryle, and Captain W. H. Tytler, has added very materially to our knowledge of this interesting and important disease. It seems to me that now is the time for settling the question of nomenclature, as the authors still associate Weil's name with the disease, although they mention that Martin and Pettit have recently pointed out how unjust this is, in view of the fact that it was described by several French authors, including Larrey (1800), Ozanam (1849), Monneret (1859), Laveran (1865), Lancereaux (1882), and Landouzy (1882), many years before 1886, when the Heidelberg professor published his paper. As there are certainly other forms of infectious jaundice, such as that of the Gallipoli epidemic, which was clinically quite distinct and was probably a result of infection with an organism allied to the *B. paratyphosus* A, the most suitable name seems to be the spirochætal jaundice, which has the advantage of being simpler than spirochetosis icterohæmorrhagica, suggested by the Japanese investigators. It is true that this name is not invariably quite appropriate, as the authors confirm the observations of Dawson and Hume<sup>1</sup> that the disease may occur without external signs of jaundice; but the name remains the most suitable of those which have been suggested, for the disease is always spirochætal in origin, and the jaundice, though inconstant, is the most characteristic symptom in the majority of cases, and appears to be constant in experimentally infected guinea-pigs.

I am, Sir, yours faithfully,  
Netley, Jan. 23th, 1917. ARTHUR F. HURST.

### PASSIVE HYPERÆMIA IN WOUND TREATMENT.

To the Editor of THE LANCET.

SIR.—Whilst applying Bier's method of treatment by passive hyperæmia to one of my own fingers from which the nail had been removed for a whitlow, I was impressed by the rapidity with which lymph exuded from the raw and granulating surface. This occurred within a very few minutes of the time of application of the elastic. Is not this effusion of bactericidal lymph precisely the result aimed at in Wright's method of treating septic wounds by hypertonic saline, and, if so, would it not be worth while to use Bier's method more frequently than (so far as my limited opportunities of observing show) is the case?

I am, Sir, yours faithfully,

R. L. GAMLEN,  
Captain, I.M.S. (retired).  
Brighton, Jan. 29th, 1917.

\* \* \* The flow of bactericidal lymph can be excited in very many ways, some being more convenient in one case and some in another.—ED. L.

<sup>1</sup> B. Dawson and W. H. Hume: Quarterly Journal of Medicine, 1916, x., 30.

THE COLLEGE OF NURSING, LIMITED.—Our Dublin correspondent writes: On Jan. 27th, at the Royal College of Physicians of Ireland, Miss R. C. Davies, matron of the Royal Free Hospital, London, and Miss Rundle, secretary of the College of Nursing, Limited, addressed an audience of medical men and nurses, with the purpose of explaining the objects of the College. They answered some of the objections said to have been put forward by Irish nurses, and a free discussion followed. It did not appear, however, that the Irish nurses are yet satisfied as to the wisdom of joining the College.

### The War.

#### THE CASUALTY LIST.

The following names of medical officers appear among the casualties announced since our last issue:—

##### Killed.

Capt. H. L. Jarman, R.A.M.C., attached S. Wales Borderers.  
*Lost in H.M.S. "Laurentio."*

Surg. F. E. Rock, R.N., was a student at Middlesex Hospital, and qualified in 1893. He was at one time assistant medical officer of health at Huddersfield, and, previous to rejoining the Royal Navy after the outbreak of war, he held the position of assistant medical officer of health and assistant school medical officer at Edmonton.

##### Wounded.

Lieut. J. A. Noble, R.A.M.C.  
Capt. M. A. McDonald, R.A.M.C.

#### DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Second Lieut. J. A. E. Freud, R.F.A., eldest son of Dr. J. A. Freud, of Rosario, Argentine Republic, and Eastbourne, Sussex.

Second Lieut. C. H. P. Maurice, Royal Berkshire Regiment, eldest son of Lieut.-Col. W. J. Maurice, R.A.M.C.

Lieut. T. S. H. Schäfer, Northumberland Fusiliers, younger son of Professor Sir E. Schäfer, of Edinburgh University.

Lieut. A. McLintock, Duke of Wellington's West Riding Regiment, second son of the late Dr. J. McLintock, F.R.S., of Edinburgh.

#### THE HONOURS LIST.

The following awards to medical officers are announced:—

##### Distinguished Service Order.

Temp. Capt. Dyfrig Huws Pennant, R.A.M.C., attached Headquarters, R.F.A.

For conspicuous gallantry and devotion to duty. He dressed and remained with three wounded men under the most intense fire. He has at all times set a splendid example of courage and coolness, and has on many occasions done fine work.

##### Military Cross.

Lieut. Daniel Davies Evans, R.A.M.C. (Spec. Res.), attached Royal Dublin Fusiliers.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in collecting and attending to the wounded under very heavy fire.

Temp. Capt. Rupert Farrant, R.A.M.C., attached Shropshire Light Infantry.

For conspicuous gallantry and devotion to duty. During the whole day he tended wounded in an open trench which was subjected to a violent bombardment. On one occasion he led a party into "No Man's Land" and brought in several wounded men.

Temp. Capt. Frank Anthony Hampton, R.A.M.C., attached Royal Scots.

For conspicuous gallantry and devotion to duty. He continually went out under very heavy fire and remained in the open attending to the wounded with the utmost bravery and coolness. He has previously done fine work.

Temp. Capt. John Samuel Levis, R.A.M.C.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination when in charge of stretcher-bearers under heavy fire. He has on many previous occasions done fine work.

Temp. Capt. Francis Cromby Macaulay, R.A.M.C.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in collecting and attending to wounded under very heavy fire.

Temp. Capt. Philip Hugh Rawson, R.A.M.C., attached South Staffordshire Regiment.

For conspicuous gallantry in action. On several occasions he rescued wounded men under very heavy fire. He set a fine example of courage and coolness throughout.

Temp. Surg. George Lee Ritchie, R.N., attached Royal Naval Division.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in collecting and attending to the wounded under very heavy fire.

Capt. Arthur Ashton Smalley, R.A.M.C. (Spec. Res.).

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in attending to the wounded, working continuously for 48 hours under heavy fire. He set a fine example throughout.

Temp. Surg. Geoffrey Sparrow, R.N., attached R.N.D.

For conspicuous gallantry and devotion to duty. He displayed great courage and determination in collecting and attending to the wounded under very heavy fire.

**Capt. Wilmot Fenwick, Aust. Med. Corps.**

For conspicuous gallantry and devotion to duty. He worked continuously for 48 hours under very heavy fire tending and dressing the wounded. He set a splendid example of coolness and courage throughout.

The *London Gazette* states that the award of the Military Cross to Temp. Capt. Francis John Morris, R.A.M.C. (announced in THE LANCET of Jan. 6th, p. 38), is cancelled, and the following is substituted: Capt. John Morris, R.A.M.C. (T.F.), attached Cheshire Regiment.

**MENTIONED FOR DISTINGUISHED SERVICES.**

The names of the following medical officers have been brought to the notice of the Secretary of State for War for distinguished services rendered in connexion with the war:—

Lt.-Col. H. G. Barling, R.A.M.C.; Lt.-Col. H. P. W. Barrow, R.A.M.C.; Lt.-Col. A. W. Browne, R.A.M.C., ret.; Lt.-Col. H. E. B. Bruce-Porter, R.A.M.C.; Col. Hon. W. B. Collins, N.Z. Med. Corps; Lt.-Col. H. Davy, R.A.M.C.; Surg. Lt.-Col. P. J. Freyer, I.M.S., ret.; Capt. P. J. Gasikin, R.A.M.C.; Lt.-Col. G. M. Goldsmith, R.A.M.C.; Maj. G. L. Gulland, R.A.M.C.; Lt.-Col. H. A. Haines, R.A.M.C.; Col. W. H. Horrocks, A.M.S.; Lt.-Col. C. J. Jacomb-Hood, R.A.M.C.; Temp. Col. E. Jones, R.A.M.C.; Surg.-Gen. W. W. Kenny, late R.A.M.C.; Lt.-Col. Sir W. Arbuthnot Lane, Bt., R.A.M.C.; Col. D. J. MacKintosh, M.V.O.; Lt.-Col. W. J. Macnamara, R.A.M.C.; Temp. Lt.-Col. Sir T. Myles, Knt., R.A.M.C.; Col. E. North, late R.A.M.C.; Lt.-Col. T. H. Openshaw, C.M.G., R.A.M.C.; Lt.-Col. W. W. Pope, late R.A.M.C.; Capt. W. A. Robertson, R.A.M.C.; Lt.-Col. G. B. Stanisstreet, R.A.M.C.; Temp. Lt.-Col. J. Swan, R.A.M.C.; Temp. Hon. Lt.-Col. J. L. Thomas, C.B., R.A.M.C. (Maj., ret., T.F.); Lt.-Col. T. B. A. Tuckey, R.A.M.C.; Temp. Lt.-Col. W. A. Turner, R.A.M.C.; Lt.-Col. G. H. Twiss, ret. pay, late R.A.M.C.; Maj. W. I. de C. Wheeler, R.A.M.C.

**CENTRAL MEDICAL WAR COMMITTEE.**

A meeting of the Central Medical War Committee was held on Wednesday, Jan. 31st, when, arising out of some correspondence, a vote of the Committee was taken as to the advisability of members of Local Medical War Committees serving on the central body. It was unanimously decided that it was an advantage to the Central Medical War Committee to have local views represented to them in a direct manner.

The Committee considered the need still existent for a large number of medical officers to serve with the Army. A valuable report from the Assessment Subcommittee and the Executive Subcommittee, dealing with the calls made on Local Medical War Committees to meet the present demands of the War Office, was placed before the Committee, when Dr. C. Buttar, chairman of the Executive Subcommittee, detailed the various sources from which officers might be obtained, mentioning the possible reduction in all estimated figures, either through rejection by the War Office as unfit for service, or through successful appeals for exemption. Colonel Blenkinsop, who was present at the meeting at the request of the Director-General of the Army Medical Service, explained how the need for medical officers in the Army was affected by sickness and wounds, wastage and resignations, and indicated the places at which officers were at the moment urgently needed. An interesting discussion showed that the work of the Central Medical War Committee had been very strenuous and thorough, but that the demands of the medical profession will for some time remain pressing.

***Medical Examination of Medical Men under 41.***

The Central Medical War Committee is receiving many inquiries from medical men who come within the terms of the Military Service Acts as to the meaning of a request they have received from the military authorities to present themselves for medical examination. This request need not give rise to any misgiving. The position of enrolled men is not affected by it, for the question of whether they will be required to accept a commission in the Royal Army Medical Corps or not is one to be settled by the Central Medical War Committee in consultation with the Local Medical War Committee concerned. So much delay has, however, been caused in connexion with past calls by the uncertainty as to whether the men warned as being likely to be called for service were or were not physically fit that the War Office has decided to have all the doctors of military age examined and to have the question of physical suitability settled. Medical men receiving such a notice from the military authorities must comply with it, but need take no further steps until they hear from the Local or the Central Medical War Committee that any other steps are needed.

**THE TRANSFERENCE OF THE TRAINING ESTABLISHMENT OF THE ROYAL ARMY MEDICAL CORPS.**

We understand that it has been decided to transfer the training of the Royal Army Medical Corps from Aldershot to Blackpool, the reason for the measure being the extreme pressure on the accommodation of Aldershot camp. The dépôt of the Corps remains at Aldershot for the time being. The Royal Army Medical Corps has always much valued its position at Aldershot because it afforded opportunities which had been wanting at Netley for keeping in touch with metropolitan hospital practice, while propinquity was also secured to the Royal Army Medical School at Millbank. The transference of the training to Blackpool will therefore be much regretted by the Corps, and would, we feel sure, have only been made in response to the urgent need of the Army.

**TREATMENT OF BURNS AND SCALDS IN THE NAVY.**

Every ship in the Navy carrying a medical officer or surgeon-probationer has been recently equipped with an outfit for the paraffin treatment of burns and scalds, as have also all naval hospitals, hospital ships, and hospital trains. The paraffin preparation at present supplied is named "ambrine" by its inventor, Dr. Barthe de Sandfort, of Paris. Attention was first called to this method of treatment in THE LANCET<sup>1</sup> and *Times*, and Sir Arthur May, the Medical Director-General of the Navy, is to be congratulated on the promptitude with which he acted in the matter. Within a few days of the articles appearing in the journals he despatched one of his staff to Paris to investigate and report, and as a result of this report it was considered that the treatment had so much to commend it from a naval point of view, that no time should be lost in putting it in the hands of the medical staff of the Navy. And no better opportunity can be imagined for a thorough test of the efficiency of the treatment, as it is well known that burns and scalds form a good proportion of the injuries met with on board ship, not only during war but also in times of peace.

Not only did Sir Arthur May obtain the necessary information promptly, but the form in which he placed "ambrine" at the disposal of medical officers has given the treatment the best possible chance. The outfit, which we have seen in use, is neat and compact, and consists of a supply of the "ambrine," a small brush, a sprayer and bellows, together with clear and precise instructions for use, the whole being contained in a portable wooden box labelled "Dressings of Burns by Paraffin Wax." The methods of use, technique, cannot be better described than in the words of the printed instructions contained in each box, which are based on the teaching of the inventor of "ambrine" and which we quote verbatim:—

**DRESSINGS OF BURNS BY PARAFFIN WAX.**

The substance contained in this outfit is a mixture of paraffin and resins, and is termed by its inventor "Ambrine." It is solid when cold and becomes fluid when heated to 140°-150° F. It can be used as a "first-aid" dressing for burns and for their subsequent treatment if considered desirable. The originator of the preparation advocates its use for all classes of burns and employs it through the whole stage of treatment, and he claims that by so doing he has had excellent results.

***Methods of Use.***

(a) *Heating.*—Place a piece of the wax in the sprayer provided, and heat the latter over a spirit lamp, or set it in a basin containing a little water which should be kept boiling for ten minutes.

(b) *Precautions to be taken.*—Care should be taken to prevent any water getting into the wax. It must be remembered that the latter does not burn the tissues at 176° F., but the smallest quantity of water present would cause scalding. With the same end in view, the burnt area should be gently dried before the application is made. While the above is being heated, prepare a few fine layers of absorbent cotton; these layers should be as thin as possible.

(c) *The dressing.*—When the wax is in a liquid state and has been allowed to cool to a temperature of, roughly, from 140° to 150° F., it can then be applied to the burnt area either by means of the spray or the brush supplied for the purpose, or by the sprayer followed by the brush. If the sprayer is used the metal should be heated all over (including the nozzle), as any coagulation of the wax at this point will interfere with the proper working of the instrument.

The flame should be kept from the wooden handle and rubber bellows. *As regards the technique.*—The sprayer is first held about 9 inches from the patient, and the area is sprayed over until it has the appearance of being covered with a thin layer of hoar-frost. The sprayer is now brought closer (say 3 to 4 inches) and the bellows briskly worked; it will then be seen that in the centre of this spray-stream the wax assumes a liquid appearance. With this liquid spray the whole of the affected part is now quickly covered. A thin layer of cotton-wool is next laid on this wax, and the whole is then again covered with the liquid wax, by the brush. It is strongly recommended that the surgeon

should first try the method by applying two or three dressings to his own hand or arm.

*Note.*—When removing the lid from the sprayer do not hold it by the handle (as the leverages may buckle the side of the instrument). It should be held by the body of the sprayer, using a cloth if the metal is hot.

*When using the brush.*—Remove the lid of the sprayer, take the brush provided, and dip it in the liquid. Now spread the latter over the wound without pressing—that is as much as possible dabbing it and not brushing it on; this operation is repeated until the glazing is complete, taking care to leave no spot uncovered. Immediately afterwards place quickly on this first wax glaze one of the thin layers of absorbent cotton, already prepared as explained above, and then, with the same dabbing movement, put on several more applications of the fluid.

If the wound is extensive the operation is done on small square surfaces successively and close together (about 4 by 4 inches). These little squares thus become part of one another.

After the preparation (which with cotton-wool forms a shell or casing) has been allowed to cool, dressings and bandages can be applied in the usual manner. The initial use of the sprayer is recommended where the area is painful.

*Removing the dressing.*—For the first few days the waxy shell must not be left in place more than 24 hours; later, if it is desired to still employ it as a dressing, it can be left for 48 hours, or even longer.

To remove the dressing, untie the bandages and expose the "shell." An incision is made in the latter by means of a blunt knife or scissors, and the whole is peeled off. The wound is afterwards bathed with boiled water and the cleansing is further perfected by washing with absorbent cotton soaked in boiled water. Then it is dried either by a current of warm air or by a piece of cotton-wool, care being taken not to rub, or cause the granulations to bleed.

Antiseptic solutions should not be used (except very weak) and care should be taken not to apply the liquid at a temperature of more than 150° F.

Heating the wax in a bath of boiling water raises its temperature to nearly 212° F.; therefore before applying it to the burn, *with the brush*, it should be removed from the water bath and allowed to stand for a minute or two, so as to reduce its temperature to below 150° F.

It is claimed for the application that:

- (1) It immediately alleviates pain.
- (2) It constitutes a warm "shell" under which the tissues are protected against outside contamination, and are, as it were, "splinted."
- (3) It can be removed without pain or injury to the newly forming tissues, and thus limits the formation of scar tissue.

If the directions are followed, the dressing of burns by paraffin wax becomes a straightforward and even simple routine; and all who recall the agony undergone by the burnt patient at the hands of experienced people trying to remedy the condition according to the usual technique, will recognise that we are bestowing high praise.

The initial use of the sprayer is considered necessary in painful cases, and desirable in practically all, not only for its very soothing effects, but also because the injured area is first covered in thereby by a fine sterile coating, and contamination by direct contact with the brush, which even with the best intentions it may be difficult to keep clean, is avoided.

The inventor of "ambrine"—Dr. Barthe de Sandfort—has used it for treatment of burns and scalds at the Hospital St. Nicolas, Issy-les-Moulineaux, for some time past, and there can be no doubt with a good deal of success. He applies it all through from the very beginning, only finishing when sound healing has taken place, and has had good results with very severe burns even of the third degree. The newly formed skin is generally found to be soft and supple, scarring is greatly diminished or absent, and recovery is accelerated.

The results of the trials with "ambrine" now being carried out in the Navy in accordance with Sir Arthur May's instructions will be awaited with interest by the profession at large.

**THE RED CROSS.**—The County of London Red Cross Fair at the Central Hall, Westminster, will be opened on Feb. 15th by Princess Patricia of Connaught.—A cheque for £430 6s. 7d. has been received by the Joint War Committee of the British Red Cross Society and the Order of St. John from Sir Frederick Ponsonby, Keeper of His Majesty's Privy Purse, the proceeds of the sale of venison from the King's estates, which His Majesty directed should be given as a donation to the Red Cross funds.—The annual report of the Gloucestershire branch of the Red Cross Society shows that at present there are 22 Voluntary Aid hospitals with 2200 beds in the county. 16,800 patients have passed through these institutions since the commencement of the war.—Up to Dec. 31st last 53,450 loaves had been despatched to British prisoners of war in Germany by the dépôt at Copenhagen under the control of the Red Cross.

**AMBULANCES FOR THE BALKANS.**—On Jan. 30th 17 ambulance cars, fully equipped, which have been presented to the London Committee of the French Red Cross by Sir Lucas Ralli, senior partner in the firm of Ralli Bros., were

inspected in Hyde Park by the French Chargé d'Affaires (M. Picot). The cars comprise a full ambulance unit, and will be under the command of Major L. Lyon Clark (late North Devon Hussars).

**THE BATHS OF SIDMOUTH (DEVON).**—At the recent annual meeting of the Sidmouth Baths Company the chairman stated that alterations and additions were to be made in the equipment of the baths in order to enable wounded officers to have special treatment. The War Office had approved of the scheme and would defray the necessary cost.

**THE WOUNDED ALLIES RELIEF COMMITTEE.**—The Committee is presenting to the Queen of Roumania, through Madame Misu, wife of the Roumanian Minister in London, drugs and surgical instruments to the value of £500, for the benefit of sick and wounded soldiers of the Roumanian Army.

**THE SENATE OF LONDON UNIVERSITY** consider it advisable in the national interest to permit matriculated students to continue their studies until the age of 18 years and 8 months, or even 19 years, provided that they receive suitable military instruction for some hours weekly. Their resolution to this effect has been sent to the War Office and to the Board of Education.

## Medical News.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.** At the First Professional Examination for the Licence in Dental Surgery held on Jan. 25th and 26th the following candidates were successful:

**Mechanical Dentistry and Dental Metallurgy.**—Leonard Harry Braibar, Bristol University; and William Henry Turner, Guy's Hospital.

**Mechanical Dentistry.**—Myer Isaac Benischowitz, Royal Dental Hospital; Christopher Egerton George Busbridge, National Dental Hospital; Herbert William Hill and Wallace Inman, Royal Dental Hospital; Herbert Myers Marshall, Guy's Hospital; Edith Mynton Norman, National Dental Hospital; Hubert John Sanders, Bristol University; and Stanley Vernon White, Guy's Hospital.

**Dental Metallurgy.**—Ralph Martin Eland, Bristol University; and Arthur Douglas Ray, Manchester University.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—A Comitia was held on Jan. 25th, Dr. Frederick Taylor, the President, being in the chair.—Dr. V. B. Green-Armytage having passed the necessary examination was admitted a Member of the College. Eighty-three candidates having passed the requisite examinations were granted Licences to practise physic.—Diplomas in Public Health were granted conjointly with the Royal College of Surgeons of England to the following candidates: Dr. G. E. Beaumont, Oxford, Middlesex, and University College; Dr. V. Borland, Glasgow and University College; Mr. S. F. Chellappah, Ceylon and King's College; Dr. Una Griffin, Royal Free and University College; Mr. S. H. Paul, Charing Cross and King's College; and Dr. Mary A. van Ingen, Royal Free and University College.—Dr. J. Michell Clarke, Dr. W. E. Wynter, Dr. James Taylor, and Dr. Herbert Spencer were elected councillors.—Sir Francis Champneys was re-elected a Representative of the College on the Central Midwives Board.—Dr. Newton Pitt was elected a Representative Governor of the University of Bristol in place of Sir William Church, who had resigned.—Sir Dyce Duckworth was re-elected a Representative of the College on the Council of Queen Victoria's Jubilee Institute for Nurses.—The President stated that he had taken part in a deputation to the President of the Local Government Board, at the invitation of the Association of Municipal Corporations, urging that unqualified practitioners should be prevented from undertaking the treatment of venereal diseases.—The President also announced that he had appointed Professor R. Saundby to be Harveian Orator, and Dr. E. S. Reynolds to be Bradshaw Lecturer for this year, and that the Council had appointed Dr. T. M. Legge to be Milroy Lecturer for 1918.—A report was received and adopted from the Representative of the College on the General Medical Council (Dr. Norman Moore) concerning the meeting of the Council held in November last.—A report was received and adopted from the Committee of Management recommending that Rugby School, which is already recognised for instruction in chemistry and physics, should also be recognised for instruction in biology.

**RÖNTGEN SOCIETY.**—A general meeting of this society will be held on Tuesday next, Feb. 6th, at 8.15 P.M., at the Institution of Electrical Engineers, Victoria Embankment, W.C. Ordinary meetings of the Society will be held

at the same time and place on the following Tuesdays: Feb. 6th, March 6th, April 3rd, May 1st, and June 5th. Members desirous of reading papers or exhibiting apparatus are requested to communicate with the honorary secretaries at the earliest possible date.

**Mr. George Gidley, of Ashburton, Devonshire, died recently in his 102nd year.**

**Dr. William Fookes Thompson has been placed upon the commission of the peace for the borough of Launceston (Cornwall).**

**Professor C. S. Sherrington will deliver a discourse on "Recent Physiology and the War" at the Royal Institution this (Friday) evening in the place of Dr. Charles Carpenter.**

**Major John Bruce, R.A.M.C., will give a short lecture and demonstration at the Dermatological Section of the Royal Society of Medicine on Thursday, Feb. 15th, at 5 P.M., on "The Treatment of Scabies with Sulphur Vapour."**

**SCOTTISH POOR-LAW MEDICAL OFFICERS' ASSOCIATION.**—The committee in their report for the year 1916 state that owing to the scarcity of medical men a number of vacancies have not been filled up, although parish councils have advertised the appointments as open to women. Correspondence with the Highlands and Islands Medical Service Board had led to the discovery that the board did not, as was supposed, guarantee to all medical officers in the Crofting Counties a position including: (1) a suitable dwelling-house, rent free; (2) the necessary outlays in connexion with the working of the district; (3) a minimum income of £300 a year. The committee therefore proposed to return to their old position of warning applicants not to go blindfold into a district where the arrangements as regards income, area, and facilities might be unsatisfactory. The annual meeting of the Association will be held in the St. Enoch Hotel, Glasgow, to-day, Friday, Feb. 2nd, at 4.30 P.M.

## Appointments.

*Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

**CUMMING, J., M.B., C.M. Glasg.,** has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Hull District of the county of Yorks (East Riding).

**GARMAN, J. M., M.R.C.S., L.R.C.P. Lond.,** Medical Officer for the Sillinge District of the Elam Union.

**IRONSIDE, EVA CONSTANCE, M.B., Ch.B. Aberd.,** Deputy Medical Officer of Health for the Buckfastleigh (Devon) Urban District Council and Acting Public Vaccinator for the Buckfastleigh District of the Tivnes (Devon) Union.

**LANGRAN, WILLIAM, L.R.C.P., L.R.C.S., L.M. Edin., L.A.H. Dub.,** Commandant, and LUMSDEN, HARRY FOOTE, M.B., Ch.B. Edin., RAMSDEN-WOOD, WILLIAM EDWARD, M.D. Cantab., RICHARDS, NORMAN LLOYD, L.R.C.P., M.R.C.S., Medical Officers to the V.A.D. Hospital, Rhoda Hill, Uplyme, Devon.

**SHARPLEY, E., M.D. Durh.,** Certifying Surgeon under the Factory and Workshop Acts for the Louth District of the county of Lincoln.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.*

**BARNESLEY, BECKETT HOSPITAL AND DISPENSARY.**—House Surgeon. Salary £200 per annum, with board, &c.

**BATH WINSLEY SANATORIUM.**—Assistant Resident Medical Officer. Salary £250 per annum, with board, &c.

**BOLESKINE AND ABERARTH, PARISH COUNCIL OF.**—Medical Officer (and Vaccinator), &c. Salary between £350 and £400 per annum.

**BOLTON INFIRMARY AND DISPENSARY.**—Female Second House Surgeon. Also Female Third House Surgeon. Salaries £200 and £180 per annum respectively, with board, &c.

**BRISTOL GENERAL HOSPITAL**—House Surgeon for six months. Salary at rate of £175 per annum, with board, &c.

**CARDIFF, KING EDWARD VII.'S HOSPITAL.**—House Surgeon for six months.

**DERBYSHIRE ROYAL INFIRMARY, DERBY.**—House Physician and Casualty Officer. Also Resident Anaesthetist. Salaries £200 per annum, with board, &c.

**EDMONTON MILITARY HOSPITAL, LONDON, N.**—Medical Officers. Salary at rate of £1 per day and keep.

**ESSEX, ADMINISTRATIVE COUNTY.**—Tuberculosis Officer. Salary £500 per annum.

**GRIMSBY AND DISTRICT HOSPITAL.**—House Surgeon. Salary £5 5s. per week, with board, &c.

**GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.**—House Surgeon. Salary £200 per annum, with board, &c.

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.**—House Physician for six months. Salary 30 guineas.

**HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON, W.C.**—House Surgeon, Assistant Casualty Medical Officer, and House Physician, unmarried. Salary at rate of £60 per annum each, with board, &c.

**HOSPITAL FOR WOMEN, SOHO-SQUARE, W.**—Female Resident Medical Officer for three or six months. Salary £80 per annum, with board, &c.

**KENT EDUCATION COMMITTEE.**—Temporary School Medical Inspector and Medical Officer of School Clinic. Salary at rate of £350 per annum.

**LEAMINGTON SPA, WARNEFORD AND SOUTH WARWICKSHIRE GENERAL HOSPITAL.**—Second Resident Medical Officer. Salary £200 per annum, with board, &c.

**MAIDSTON, WEST KENT GENERAL HOSPITAL.**—Senior House Surgeon. Salary £250 to £300 per annum and all found.

**MANCHESTER ROYAL INFIRMARY.**—Resident Medical Officer. Salary £225 per annum, with board, &c.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.**—Female Co-examiner to School of Massage.

**NORTHERN MUNITIONS FACTORY.**—Female Assistant Medical Officer. Salary £400 per annum.

**NOTTINGHAM AND MIDLAND EYE INFIRMARY.**—Female Resident House Surgeon. Salary £120 per annum.

**PORTREE, ISLAND OF SKYE.**—Parish Medical Officer and Public Vaccinator. Salary about £480 per annum.

**ROTHERHAM HOSPITAL.**—Junior House Surgeon. Salary £150 per annum, with board, &c.

**ST. MARK'S HOSPITAL, CITY-ROAD, E.C.**—House Surgeon. Salary as arranged, with board, &c.

**ST. PETER'S HOSPITAL FOR STONE, &c., HENRIETTA-STREET, COVENT GARDEN, W.C.**—Junior House Surgeon for six months. Salary at rate of £75 per annum, with board, &c.

**SALFORD ROYAL HOSPITAL.**—Honorary Physician for Diseases of the Skin.

**SHEFFIELD UNION HOSPITAL, FIRVALE.**—Female Resident Assistant Medical Officer. Salary £250 per annum, with rations, &c.

**STAFFORDSHIRE EDUCATION COMMITTEE.**—Female Assistant School Medical Inspectors. Salaries at rate of £400 per annum.

**SUNDERLAND ROYAL INFIRMARY.**—Female House Surgeon. Salary £150 per annum, with board, &c.

**UNIVERSITY OF LONDON.**—External Examiners.

**WELSH METROPOLITAN WAR HOSPITAL, WHITCHURCH, NEAR CARDIFF.**—Resident Medical Officer.

**WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.**—Resident Surgical Dresser.

**THE CHIEF INSPECTOR OF FACTORIES, HOME OFFICE, LONDON, S.W.,** gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Cleobury Mortimer, Salop.

## Births, Marriages, and Deaths.

### BIRTHS.

**ARCHER.**—On Jan. 23rd, at Monckton-road, Alverstoke, Hants, to Ada Caroline, wife of Charles W. Archer, F.R.C.S., Temporary Surgeon, R.N.—two daughters.

**HURRY.**—On Jan. 25th, at Berry Lodge, Shoreham-by-Sea, the wife of Captain H. R. Hurry, R.A.M.C., of a son.

**PATTISON.**—On Jan. 26th, at The Cottage, Hollow Meadows, Sheffield, the wife of C. Lee Pattison, M.B., B.S. Lond.—a daughter.

**STEVENSON.**—On Jan. 26th, at Burpham House, Farsham, Hants, the wife of W. Sinclair Stevenson, M.D., of a son.

### MARRIAGES.

**BREWITT-TAYLOR—ELLIS.**—On Jan. 27th, at Rosslyn Hill Chapel, Hampstead Raymond Brewitt-Taylor, M.B., younger son of C. H. Brewitt-Taylor, of China, to Evelyn, youngest daughter of Henry Ellis, of Potter's Bar.

**RAFFLE—MONRO.**—On Jan. 24th, at St. Michael's Church, South Shields, Captain Wilfrid Raffle, R.A.M.C., attached Coldstream Guards, to Nora, only daughter of Mr. and Mrs. Charles Monro, Hampstead, N.W.

**ROMER—WILLIS.**—On Jan. 25th, Harry Romer, M.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S. Eng., to Clara Lillian, second daughter of the late Mr. Newman Willis, of Finedon, Northants.

**VERTUE—WALLACE.**—On Jan. 31st, at St. Saviour's Cathedral, Southwark, Lieutenant Henry St. Hill Vertue, R.A.M.C., to Clementina Margaret, daughter of the late Rev. W. J. Wallace, formerly Rector of Mount Mellick, Queen's County, and of Mrs. Wallace, Albert-road, Sandycove, Co. Dublin.

### DEATHS.

**FARR.**—On Jan. 26th, suddenly, at Heath House, Andover, Ann Lawrence Augusta Mabel, the most dearly loved wife of Ernest A. Farr, J.P., and only daughter of the late Major-General and Mrs. I. L. Bolton, of Lt. Chasse, Jersey.

**HUMPHREYS.**—On Jan. 16th, at Richmond, Surrey, Henry Humphreys, M.A., M.D. Cantab., M.R.C.P., late Fellow St. John's College, Cambridge, aged 72 years.

**SANDIFER.**—On Jan. 23th, Henry Stephen Sandifer, M.D., F.R.C.S., of Dawson-place, W., aged 51 years.

**WILKINSON.**—On Jan. 25th, at The Maples, Blackheath, S.E., Francis Tichborne Wilkinson, Lieutenant-Colonel, R.A.M.C. (retired), aged 59 years.

**N.B.—A fee of 5s. is charge for the insertion of Notices of Births, Marriages, and Deaths.**

## Notes, Short Comments, and Answers to Correspondents.

### PUBLIC HEALTH IN NEW SOUTH WALES.

THE most important matters connected with public health administration in New South Wales during 1914 are dealt with in the report by Dr. Robert T. Paton, the Director-General of Public Health for the State, recently issued (Sydney: W. A. Gullick, Government Printer, 1916, price 7s.). Disposal of refuse, the working of the Pure Food Act of 1908, the standardisation of Australian manufactured food products, supervision of the meat-supply, treatment of tuberculous patients in State sanatoria and by special dispensaries, and fresh legislative measures for checking the spread of disease (including notification) and anti-typhoid inoculation are the chief subjects considered in this report. Further details are given in a series of departmental reports. Great care is taken in the inspection of foodstuffs; it was found necessary in many cases to take drastic action, condemn, and destroy large quantities that were totally unfit for human consumption; amongst other things, 53 tons of dried fruit, found to be riddled with insects, were seized and condemned. Dairies and slaughter-houses are inspected under the Public Health Act, but owing to the limited staff can only be visited once in eighteen months. The supervision of the meat export trade is of great importance to the State (as well as to the enormous numbers of persons in the United Kingdom who derive the greater part of their meat-supply from this source). During 1914 there were 437,429 packages of canned meats, and 1,925,756 carcasses of mutton and lamb exported, besides large quantities of beef, veal, and meat extracts. The health authorities in Europe and in the United States require a high standard for the inspection and sanitary handling of the meat exported from the Commonwealth. By arrangement with the Commonwealth Government a few years ago all inspections of meat in New South Wales were handed over to the Public Health Department of the State; the work is carried out by an experienced veterinary surgeon, assisted by fifteen inspectors. Meat for home consumption is inspected in similar manner. The prevention of venereal diseases and tuberculosis receives special attention; for the former it is recognised that the provision of adequate and easily accessible means of treatment is the only method by which the affected persons can be secured from the more disastrous effects of these diseases, and other persons protected from contracting infection. Two night-clinics have been opened, the numerous attendances at which have demonstrated the absolute necessity of taking special steps in this direction. For combating consumption nurse-inspectors are provided to visit and advise patients as soon as their condition comes to the knowledge of the health department; the cases are then classified into (a) those that can be cared for in their own homes and are well enough to attend the dispensaries; (b) those requiring removal to a sanatorium; (c) those in whom the disease is so far advanced as to render permanent medical care and maintenance necessary. The principal State sanatorium at Waterfall contains 370 beds; in addition at the Rookwood State Hospital there is accommodation for 100 male patients. It is intended to erect pavilions at Waterfall for the reception of an additional 100 males and to withdraw tuberculosis cases from Rookwood. The death-rate from pulmonary consumption has decreased most notably during recent years; in 1885 it was 1163 per million, in 1913 it was 669. Anti-typhoid inoculation has been carried out in the case of all troops leaving for active service in Europe or elsewhere since the beginning of the war, two inoculations having been given to about 18,000 men and vaccine supplied sufficient to protect a further 50,000. Only four persons were found to be suffering from leprosy during 1914. A considerable number of the Public Health staff—some 20 in all—were called up for military duty during the year; much work was also carried out by the medical officer of the department in advising the military authorities in regard to camp sanitation, examination of food-supplies, &c. The report by Dr. J. Burton Cleland on work done in the Bureau of Microbiology is a record of nearly 20,000 examinations, micro-biological, pathological, and medico-legal, as well as of investigations into various special subjects by the director and his assistants. Numerous illustrations, charts, and diagrams add to the value of this record of public health progress in New South Wales during 1914.

### THE PREVENTION OF VENEREAL DISEASES.

*To the Editor of THE LANCET.*

SIR.—Now that the experiments of Metchnikoff and Roux in 1904 upon apes have confirmed the practice of M. Cumanus, who, in 1495, recommended the use of mercurial ointment in the prevention of syphilitic infection, one may hope that even in England, to-day, one will not be accused of "gross

precipitancy" in suggesting that all chemists will put up for sale little cases containing drug preventives against gonorrhoea, chancre, and syphilis. Some years ago I obtained a case from a firm of chemists in Berlin, where it was being sold publicly at about two marks. Our Navy and Army Services have at last recommended it. No doubt the preventives will be a very great financial loss to doctors and chemists. One firm told me that it would mean a loss to them of about £8000 a year. Some years ago I had a large number of cases made up, and if anyone wishes to obtain a sample box for the use of males I will send one to any doctor or chemist on receipt of 5s. I have estimated that about £96,000,000 are yearly expended upon prostitution and its accompanying conditions in the United Kingdom, and if venereal diseases could be reduced even by 75 per cent. this would be a great saving to voluntary and Poor-law hospitals and in asylum expenditure.

Liverpool, Jan. 29th, 1917.

I am, Sir, yours faithfully,

ROBERT R. RENTOUL.

### "THE NEW HAZELL ANNUAL AND ALMANACK" AND "WHITAKER'S ALMANACK."

THESE two reference books, which every well-informed public, professional, and business man will find frequent occasion to consult, have appeared as usual in spite of the difficulties of compiling and publishing under war conditions. The first-named, which is in its thirty-second year of issue, has now become "The New Hazell Annual and Almanack," and is published by Messrs. Henry Frowde and Hodder and Stoughton at 3s. 6d. net. The scope has been extended, and besides containing recent and authoritative information concerning the British Empire and the nations of the world the Almanack contains much useful astronomical and cognate matter. Adequate space is given to the events of the war, the trade of the future, and the like, while an exhaustive index facilitates ready reference. Although appearing before the end of 1916, an inset page gives the personnel of the present Government.—"Whitaker's Almanack," appearing a week or two later, is now in its forty-ninth year, and the reader may be assumed to have a general familiarity with its contents. Owing to the increased cost of production the price has been raised from 2s. 6d. to 3s. 6d. net. Full value is given for the money in the information concerning the Government, finance, population, commerce, and statistics of the nations of the world, while the astronomical details are as complete and accurate as always. A new and important feature is a series of short articles on the industries of the British Empire, each written by an expert in his own department. A page is devoted to a summary of the efforts now being made to combat venereal diseases, and another to the progress of the past year in the field of sanitation.

### THE CONSERVATIVE TREATMENT OF BURNS AND SCALDS.

*To the Editor of THE LANCET.*

SIR.—I notice a very valuable contribution in your issue of Jan. 27th by Mr. G. J. O'Reilly upon this subject. I have upon several occasions been in attendance upon severe cases of scalds, one notable case being when a vat of boiling sugar burst its hoops during the process of refining and severely scalded two workmen from head to foot. Upon another occasion a man became severely burnt upon the trunk, legs, arms, and face by an explosion of petrol upon a motor-launch.

In these cases, as well as in some others, I have adopted the method described by Mr. O'Reilly—viz., a large dose of opium and rest without attempting to remove the clothing. The results could not have been better.

I am, Sir, yours faithfully,  
CHRISTOPHER KEMPSTER.  
Harley-street, W.C., Jan. 30th, 1917.

### ANNUAL REPORTS OF THE LOCAL GOVERNMENT BOARD.

Dr. J. H. L. Cumpston, Director of Quarantine for the Commonwealth of Australia, has solicited our help in obtaining a complete set of the Annual Reports of the Local Government Board of England and Wales for the medical library at the Federal Quarantine Bureau. Prior to the publication of the present series in 1874 there were issued Annual Reports of the Medical Officer to the Privy Council, which are now of definite historical value, and it is a complete series of these earlier volumes which it is desired to obtain for the library. Dr. Cumpston states that through the courtesy of the Local Government Board he has secured a number of these volumes, but the first report and the third to ninth inclusive are missing. Any of our readers who know of the existence of copies of these reports should communicate direct with Dr. Cumpston, at the Federal Quarantine Bureau, Spring-street, Melbourne.

*Esculapius.*—The description of the position may be substantially accurate; we are inclined to think that some of

the stricture is deserved, but our leading article was written precisely with the purpose of avoiding recrimination at this juncture.

**W. R. B. (Newfoundland).**—The outlook for the patient is not very favourable at her age. Delusions if taken at their earliest stage are often amenable to treatment. The co-operation of a competent alienist should be obtained.

**W. A. W. and Others.**—The interesting devices for first-aid will be likely to attract the attention of Red Cross officials and workers if exhibited in the museum of the College of Ambulance, 3, Vere-street, London, W. Application should be made to Colonel James Cantlie at that address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

## Medical Diary for the ensuing Week.

### SOCIETIES.

**ROYAL SOCIETY,** Burlington House, London, W.

**THURSDAY.**—Papers:—Lord Rayleigh, Q.M.: On the Dynamics of Revolving Fluid; Prof. H. Lamb: On the Deflection of the Vertical by Tidal Loading of the Earth's Surface; Mr. G. F. Brush and Sir R. Hartley: Spontaneous Generation of Heat in Recently Hardened Steel.

**ROYAL SOCIETY OF MEDICINE**, 1, Wimpole-street, W.  
MEETINGS OF SECTIONS.

Wednesday, Feb. 7th.

**OPHTHALMOLOGY** (Hon. Secretaries—Himore W. Brewerton, Arthur W. Ormond): at 8.30 P.M.

*Clinical Case:*

Mr. G. Hartridge: (?) Rupture of the Optic Nerve.

*Papers:*

Mr. Arnold Lawson: Three Cases of Fur Infection of the Conjunctiva.

Mr. P. C. Bardsley: The Retinal Signs of Arterio-sclerosis compared with those due simply to Increased Blood Pressure.

Friday, Feb. 8th.

**CLINICAL** (Hon. Secretaries—David Forsyth, T. P. Legg): at 8 P.M.

*Cases:*

Dr. Parkes Weber: (1) Congenital Non-familial Jaundice without Splenomegaly in an otherwise Healthy Man aged 50 years; (2) Acro cyanotic Type of Sclerodactyly with commencing Generalised Scleroderma of Face and Chest; (3) Cases of Acromegaly.

*Paper:*

Dr. Parkes Weber: Two Cases of Primary Cancer in the Liver in one of which Thrombosis of the Inferior Vena Cava occurred.

**ROYAL SOCIETY OF ARTS,** John-street, Adelphi, W.C.

**MONDAY.**—4.30 P.M., Cantor Lecture:—Prof. A. B. Pite: Town Planning and Civic Architecture. (Lecture II.)

**WEDNESDAY.**—4.30 P.M., Dr. R. F. Fox: The Future of British Spas. RÖNTGEN SOCIETY, Institution of Electrical Engineers, Victoria Embankment, W.C.

**TUESDAY.**—8.15 P.M., General Meeting. Paper:—Mr. E. B. F. d'Albe: Some Properties and Applications of Selenium.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**POST-GRADUATE COLLEGE,** West London Hospital, Hammersmith-road, W.

**MONDAY.**—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

**TUESDAY.**—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

**WEDNESDAY.**—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Parfitt: Operations.

**THURSDAY.**—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

**FRIDAY.**—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

**SATURDAY.**—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Parfitt: Operations.

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN,** 49, Leicester-square, W.C.

**TUESDAY.**—4 P.M., Dr. J. L. Bunch: Some Common Skin Diseases.

**WEDNESDAY.**—5 P.M., Dr. W. Griffith: The Pathology of Diseases of the Skin.

**THURSDAY.**—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Coccus Diseases of the Skin and Hair.

**ROYAL INSTITUTE OF PUBLIC HEALTH,** Lecture Hall of the Institute, 37, Russell-square, W.C.

*Courses of Lectures and Discussions on Public Health Problems under War and After-war Conditions:*

**WEDNESDAY**—4 P.M., Lecture IV.:—Lady Barrett, M.D.: The Role of the Midwife and the Protection of Motherhood. Prof. E. W. Hope, Miss R. Paget, Miss J. Halford, and Dr. C. Berkeley, have promised to take part in the discussion.

### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To the EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C.

### MANAGER'S NOTICES.

#### VOLUMES AND CASES.

VOLUMES for the second half of the year 1916 will be ready shortly. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half-year's numbers (inland edition) are now ready. Cloth, gilt lettered, price 2s., by post 2s. 4d. To be obtained on application to the Manager, accompanied by remittance.

#### ALTERATION IN THE PRICE OF "THE LANCET."

INCREASED war expenses and cost of production necessitate an increase of the price of THE LANCET. Commencing with the new year, the price was raised to 8d. The rates of subscription remain as revised in October.

#### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

#### TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscription given on page 6.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

#### NEWSPAPERS FOR NEUTRAL COUNTRIES.

Newspapers are not at present being sent forward to neutral European countries unless posted direct from the office of publishers or newsagents who have obtained permission from the War Office for this purpose. The Publisher of THE LANCET has obtained the required permission, and he will forward copies direct from the Office to any neutral country on receipt of instructions.

#### METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Jan. 31st, 1917.

LIEUTENANT, R.A.M.C. (T.); LATE ASSISTANT SURGEON TO GLASGOW  
ROYAL INFIRMARY.

*With a Prefatory Note*

BY SIR ANTHONY BOWLBY, K.C.M.G., K.O.V.O.,  
TEMPORARY SURGEON-GENERAL AND ADVISORY CONSULTING SURGEON  
TO THE BRITISH ARMIES IN FRANCE.

**PREFATORY NOTE.**

I HAVE been invited by the surgeons responsible for this record to preface their communication with an explanatory statement of the surgical conditions in which their work was done, and a knowledge of these will, I think, be of interest. It is well known that most surgical operations at "the Front," including those on the abdomen, are performed in the casualty clearing stations, and a large number of the latter are established at suitable places behind the firing line. At two points, however, it was not possible to place so large a unit as a casualty clearing station exactly where it was required, and as a result of this smaller units were established, such as "emergency hospitals," to deal with those patients who could not easily be taken farther back. It was at the larger of these that the authors of this communication did their work, and in addition to treating a certain number of very serious wounds of the chest and other regions they were called upon to take charge of most of the cases of abdominal wounds occurring in their area. The cases here recorded all form a consecutive series.

The hospital was housed in a good, modern, steam-heated village hospice. It had already one small operating theatre and another was quickly added. The proximity of several casualty clearing stations, with equal equipment for operations, made it possible effectually to prevent overcrowding of the hospital or overworking of the staff, for, if the latter became unduly pressed, suitable cases could always be sent to the casualty clearing station, and only the worst class retained. By this arrangement also it was easy to prevent any patient being kept waiting an unduly long time, and so to give him the best chance of recovery.

I am in complete agreement with the authors in their expressions of opinion as to the cases that should not be operated upon, and I would specially emphasise the advisability of leaving alone almost all patients shot in the region of the solid viscera, and particularly "through and through" the liver, for I am sure that I have more often seen harm than good come of surgical interference. There are certainly some exceptions to this rule, but not many. I would also lay especial stress on the advisability of not operating when more than 36 hours have passed since the infliction of a wound in the intestine area. Out of the many hundred patients who have been operated upon I know of only three or four cases of recovery after so long a delay. On the other hand, I have seen a certain number of cases such as are alluded to in this paper where operation has done more harm than good by disturbing recently formed adhesions and early processes of repair. It can no longer be doubted that patients with perforations of the hollow viscera can recover if the lesion is not too large, even though such recoveries are rare, and very few in proportion to the recoveries after early operation. It must also be remembered that many missiles have been

known to pass across the stomach and intestine areas without wounding these viscera, and it is therefore not to be supposed that a patient who is not operated upon has no chance of recovery. I have seen many who have recovered, and I am sure that the advice given by the authors is advice that should, with rare exceptions, be followed.

This record of 500 operations for gunshot wounds of the abdomen performed in a single hospital is, I suppose, unique, and it consequently gives to the opinions of the authors a corresponding value. All surgeons still employed in the treatment of such cases will especially appreciate the caution with which the authors draw their conclusions, and will value their advice the more.

A table will be found in this paper giving the results of our first 500 operations for abdominal war wounds, but the object of the paper is rather to summarise the results of our experience as to diagnosis and treatment of these cases than to attempt any elaborate description of them. We apologise in advance to readers engaged in similar work for many statements which will appear elementary or obvious to them but may be of use to even experienced abdominal surgeons undertaking this work for the first time.

The patients arrive direct from the Field Ambulances who label and send by special car all abdominal or doubtful abdominal cases. The time elapsing between wounding and arrival naturally varies considerably. A large number of patients have been received as early as three hours after the infliction of the wound, but the average is a good deal higher than this, and with the advance of the line and the more mobile conditions of fighting the time has tended to increase. For the benefit of those without experience of the Front it should be pointed out that the delay, which, of course, is quite unavoidable, occurs in getting the wounded men out of the battle area, only a small fraction of the time is occupied in the transfer by motor ambulance on the road, so that the difficulty of the time element is not entirely solved by simply establishing hospitals very close to the line—a mile or two either way is unimportant.

*Time Element in Prognosis and Treatment.*

It may be as well at this juncture to discuss the above point. Statistics are fallacious; they may show but little difference in the mortality of a series operated on four hours after wounding and another in which eight or nine hours have elapsed. The reason is that patients who were operable four hours after the wound may have become inoperable or died before eight hours have gone by, and the second series will necessarily contain cases with less severe injuries than the first.

From a careful comparison of similar cases we are quite positive that the time element is of the highest importance, and that an abdominal patient's chances diminish with every hour of delay.

The vast majority of our patients have reached us within nine or ten hours and a large percentage in half that time, but a certain number of cases arrive at much later periods, up to three or four days in the case of men who have been lying out. The treatment of such late cases must be entirely different from the early ones. It is nearly always wise to adopt an expectant attitude. If the patient is in operable condition after 48 hours it may be assumed that the visceral injury is not severe and haemorrhage has entirely ceased, while Nature has made some effort to deal with the condition.

Every case must be judged on its own merits, but operation thus late has a very high death rate. As a working rule we should say that a man in fair condition who has been wounded more than 36 hours should always be watched, unless there is some clear indication that there is a condition which must be fatal without interference. In cases much later than this—four or five days—here is usually obvious general peritonitis, and here it is wisest simply to drain the pouch of Douglas through a small incision, an operation of a few minutes only. We have had several successful cases of this kind in which doubtless intestinal wounds had been closed by adhesions.

It is most necessary in late cases of this kind to bear in mind the fact that all unoperated cases are not fatal, that severe visceral injuries can be and are cured by natural means, and that, speaking generally, while operation under suitable conditions enormously increases the patient's chances

<sup>1</sup> A summary of the facts and opinions contained in this paper has been read at a meeting of the Fifth Army Medical Society in France.  
No. 4876

of recovery, it can hardly be said that it is impossible for any patient to recover without it. We know that the mortality of large series of cases operated upon is as near as possible 50 per cent. We have no actual data as to what the mortality would be if the same cases were left without operation, but there is some reason for supposing that it would be somewhere in the region of 90 per cent. In many individuals, however, the patient's condition may make it certain that his chances of surviving operation will be represented by a number much below the average of 50 per cent., while it may be that in the same individual the nature of his wound and the probable injury present will render it likely that he would have a much better than 10 per cent. chance if left. And it is where one believes that a case is so much below the average of one class and above that of the other that the figures are reversed, that expectant treatment is adopted.

#### *Diagnosis and Prognosis on Admission.*

Two questions are continually arising when a new patient is examined. Is he fit to stand operation? Is he suffering from a true penetrating abdominal wound with injury to hollow viscera? Of course, a large number arrive in whom neither of these points is doubtful, but in perhaps half one or other question will come up, and to some of them both will apply. The determination of the answer to these questions is undoubtedly by far the most difficult problem which the surgeon has to face, and it is here, far more than in actual operating, that experience is of value.

A detail we have found most helpful is the establishment of an observation ward. This ward is on the ground floor, is furnished with beds with blankets only, and no patient remains in it long. Into it are sent all doubtful cases, and, in addition, those hopelessly moribund and those who can be pronounced off-hand to have non-penetrating wounds and who are merely waiting for transport to a clearing station. It is in connexion with the doubtful cases that this ward is so valuable. They cannot be left on stretchers, and we have found that if they are admitted to the ordinary wards and mixed with operation cases they inevitably tend to be overlooked for hours during the extreme times of stress and hard work which occur in heavy fighting. In the observation ward each bed is prominently labelled with the name of the surgeon under whom its occupant has been admitted, and the surgeons make a practice of constantly visiting this ward throughout the day, however busy. Where a number of patients collect for operation the best way to arrange the order in which they shall be taken is to leave till last and for further consideration the *doubtful* cases, and of those undoubtedly requiring operation to take invariably the men in best condition and the most hopeful cases first.

To discuss first the question. Is a given patient well enough to stand operation? The obviously moribund man—cold, pulseless, and dying—presents no difficulty, while, on the other hand, there is as a rule no doubt about the patient whose condition is good and who has been wounded four or five hours only. There is no question at all that if there is the least doubt as to whether or not there is an injury to hollow viscera, such patients should all be operated on at once. In them the actual shock of laparotomy is not a danger to life, so that if nothing is found there is no harm done, while if there is even a small visceral wound it can be closed in time to be of determining value in the issue of the case.

The difficulty lies with the patients whose condition is poor, who have been wounded for many hours, and who may present the additional problem of the uncertainty of diagnosis. The main principles which govern one's decision in these cases are as follows. If there is no doubt at all that the patient has a serious visceral injury which must be almost certainly fatal without operation—for example, a protrusion of injured intestine—he should be operated upon unless actually moribund. But he will often benefit by a delay of two hours. We have found by experience of many cases that a most marked improvement often occurs if a patient is kept in the ward, warm and at rest, for an hour or two. On the other hand, experience has also shown that a patient who shows no sign of improvement in two hours seldom recovers sufficiently to be operable in any less period than 30 or 40 hours.

Supposing, upon the other hand, that the patient's condition is bad but not inoperable, and at the same time there is doubt about the diagnosis of a severe injury to hollow viscera, the surgeon has to balance in his mind the chance

the patient will have after operation with the chance that he has an injury from which he will not reasonably recover without it. We should say in such cases where the one certain fact is that operation is going to be very dangerous, give the patient the benefit of the doubt by not operating.

#### *Diagnosis of Penetrating Abdominal Wounds.*

To turn now to the second question which arises in examining a new patient—Has he a penetrating wound and is there an injury to a hollow viscus? A point may be mentioned at once which is of importance. A man may have a severe injury to a hollow viscus without penetration of the peritoneum. This is particularly the case where the missile has torn the abdominal wall and bared, but not entered, the parietal peritoneum. We have had more than one such case in which the subjacent loop of small intestine was torn almost in two.

Another preliminary point which also occurs is the question of operation for wounds of solid viscera. Owing to their occurrence in conjunction with other wounds, injuries to the solid viscera are frequently encountered and treated in the course of an operation; but supposing that it is believed that only a solid viscus is injured, is operation indicated? We consider that it is not, with the possible exception of a kidney wound in a man whose condition is good. Wounds of the liver are seldom, if ever, benefited by operation; if very severe they are fatal, and if not severe the haemorrhage has usually ceased, and the surgeon checks by packing or suture the haemorrhage he has created by interference. The same applies to small wounds of the spleen. It is only in an obvious spleen wound where the patient is plainly suffering from haemorrhage more than shock that an operation is indicated with a view to splenectomy.

So that, speaking generally, the essential point in diagnosis is the injury of hollow viscera. There is, of course, a type of case which presents no difficulty—that in which there is a protrusion of intestine or an escape of intestinal contents, fluid, or gas through the wound, or where an injury to a viscus can be felt or seen through the wound. Sometimes surgical emphysema due to intestinal gas may be felt beneath the skin, while in one case gas had escaped along the cord and distended the scrotum.

With regard to cases with protrusion of viscera, the most important point, of course, is the condition of the intestine, whether injured itself and whether strangulated. In the event of its being neither the prognosis is not very bad. We have had a case in which the whole small intestine, the transverse colon, and the great omentum were prolapsed through the wound; it was covered with mud and wrapped in a khaki shirt, and had been so for eight hours; there was no strangulation or injury. The intestine was roughly cleaned and rapidly returned under anaesthetic, and the man made a good recovery. On the other hand, where there is a necessity for resection in these cases they are nearly always fatal. Projecting omentum, in itself not a serious condition, when found to occur, nearly always denotes a visceral injury. In this way it is an indication for operation.

The next type of case to be considered is the "through-and-through" wound. Here it is often possible to settle the diagnosis by a consideration of the line of direction of the wound upon anatomical grounds; but when this is done the line must be most carefully contemplated. With an entry in the flank and an exit by the umbilicus—for example, a wound which on a casual glance would seem to pass right through the peritoneal cavity—the wound may upon careful consideration be found to lie wholly in the muscles, while there are several fallacies in connexion with through wounds in the pelvis and upper abdomen.

The only advice one can give is to carefully consider the anatomy of the part. Remember especially the high position of the splenic flexure, and, lastly, if all other symptoms and signs are against a visceral wound do not depend on anatomical considerations alone.

The degree of dilatation of stomach or bladder and the position of the diaphragm at the moment of being hit are factors impossible to determine, while lastly, it should be remembered that men are not hit in the position in which they are examined—but often with the back extremely bent. Nevertheless the first and most important step in diagnosing these cases is a careful attempt to get all possible information from the position and nature of the wound. Exploration by finger and probe should be done wherever possible.

The final type of case remains in which the diagnosis has to be made from symptoms and an examination of the abdomen alone. It is, of course, a truism with everyone who has seen many of these cases that wounds in the chest alone may give all the signs of an abdominal injury, while wounds in the back and buttocks which give rise to retroperitoneal haematomata may set up marked abdominal rigidity and tenderness.

First as to *symptoms*. Pain is an uncertain and misleading one, especially in view of the fact that so many of these patients have had large doses of morphia. There is fairly frequently in true visceral wounds a history of intense pain a few minutes after the wound, passing off later. We have frequently noted shoulder pain in wounds of the diaphragm—an interesting referred pain which has been described before.

Vomiting is of distinct value in diagnosis. A majority of all our patients with visceral injuries had vomited before admission, and a minority only of those cases in which abdominal penetration was suspected and which subsequently proved not to be the case. Vomiting is particularly common in stomach injuries, and the absence of haematemesis in no way negatives such. A history of the passage of flatus since the wound is against any wound of the colon, especially the descending colon.

A last point of importance is to notice carefully the patient's appearance. A normal facial appearance is very greatly against a severe abdominal lesion, even if the pulse is bad, while an appearance of extreme shock may give a better hint of the truth than the pulse.

#### *Abdominal Signs.*

*Rigidity* and absence of free movement is of the utmost importance from a negative point of view. Its complete absence almost precludes a visceral injury; on the other hand, its presence may be due to a number of other causes—chest wounds, retroperitoneal haematoma, or injury to abdominal wall alone.

*Tenderness* is a far more valuable positive sign. Its undoubted presence at some little distance from the wound, and especially at the other side of the abdomen, is almost diagnostic of a visceral injury. There are, however, two other possibilities—haemorrhage in the peritoneum alone may produce it and haemorrhage in the tissues of the anterior abdominal wall will actually produce the most extreme tenderness. We have not found the attempt to define areas of hyperesthesia of any value.

*Percussion signs* are peculiarly fallacious and valueless in these cases; we attach almost no importance to them. *Rectal examination* is seldom of any value. *The passage of a catheter* may afford valuable information where injury to the urinary tract is suspected.

The last question in regard to diagnosis is as to whether to explore or to wait in a case in which it is impossible to at once make up one's mind. The deciding factor is the patient's condition. As has been said before, if this is sufficiently bad to reduce his chances of recovery after operation to probably 1 in 10 or even 1 in 5 it is far better not to operate, since even with a perforating visceral injury his chances when left may be as good as this. On the other hand, if the patient's condition is good, so that operation presents very little risk, and the wound is so recent that possibly serious visceral injury is present, it is far better to explore; if necessary, a very small incision may be made in the middle line and a swab inserted into the pouch of Douglas, to determine the presence or absence of blood. On the whole, it is far more satisfactory to explore than to wait and see when dealing with doubtful wounds in patients recently wounded and in good condition. We have done a number of such laparotomies with negative results, and the few who have died have all had serious complicating limb or other wounds.

However, occasionally the existence of a hollow viscus wound is so exceedingly doubtful that it is unjustifiable to operate. In that case, if the patient is watched, look rather for an improvement which should take place than expect the presence of visceral wound to soon render the patient worse. Such cases frequently remain quiescent for long periods and then suddenly and rapidly take a turn for the worse. A rising pulse-rate (in the absence of an increasing temperature) is nearly always an indication to operate even if the man is quite comfortable.

#### *Contra indications to Operation.*

The only complete contra-indication that we observe (apart from the condition of the patient) is a complete spinal lesion with paralysis. With such diagnosis is almost impossible—since it will give every abdominal sign and symptom without penetration, and in addition the prognosis, if operation is done, is practically hopeless. Those who encounter abdominal wounds for the first time are warned against overlooking a spinal lesion. Every patient should be asked to move his legs.

An almost complete contra-indication is a wound of the chest definitely involving lung (with haemoptysis or surgical emphysema). With such the mortality after operation is enormous; our only cases of recovery had solid viscera wounds from which they might have recovered if left. We are of opinion that such patients' chances are almost always better if left alone. Operation should be confined to such a rare case as where, with protruded viscera or otherwise, a hopeless abdominal condition can be actually seen, and in addition, for some reason, the patient's general condition is reasonably good.

Serious other wounds form an important complication in many cases. Where there is a limb wound which demands amputation perhaps the best chance is to do the abdominal operation first and risk the leaving of the amputation till a few days later. If both must be done together it is possible to get an additional surgeon to amputate while the abdomen is being operated on. We have not had a successful case of this kind, but in one which survived for some days the patient appeared to suffer less shock than would have been likely if the operation had been prolonged to over two hours by doing the two successively.

#### *Operative Measures.*

*Anæsthesia.*—Most of our cases have been given open ether with or without chloroform; atropine is usually given previously. Shipway's warm ether apparatus has been used lately with excellent results. The anaesthetic is often difficult, and experienced anæsthetists have proved their worth.

*Salines.*—It will be convenient to discuss now the giving of salines before, during, and after operation. The first point, confirmed again and again in this hospital, is that salines are of little use in shock and of the utmost value in haemorrhage. Recent work on the specific gravity of the blood in these conditions has thrown some light on the cause of this phenomenon. Unfortunately in most abdominal cases both factors are present, but it is usually easy to convince oneself that the value of the saline varies with the proportion of the haemorrhage element to the shock element. Intravenous saline has sometimes been given to bad cases in the observation ward, but has been found useless. In severe shock the effect is momentary, while in haemorrhage there are obvious dangers in giving it until the condition has been ascertained or is about to be dealt with. Rectal saline is also of little use here, as in severe cases it is not readily absorbed, while there is always the danger of its mechanically harming the abdominal condition, unless a large intestine wound can be obviously excluded.

*Saline during operation.*—In cases whose condition is good or fair we have used subcutaneous saline with Lane's bag extensively; Oi. or Oii. with 1 c.c. of pituitrin, and occasionally 3 i. of adrenalin solution being infused during the operation. It is only right to mention that in two cases this method has been followed by cellulitis. Both were fatal, with gas gangrene of the original wound, and it appears that there was an infection in addition at the site of the saline injection. In neither case was it the cause of death, but it shows the method has its dangers. In more severe cases with haemorrhage we use intravenous saline; Oii. or more are given with brandy 3 ii., adrenalin solution 3 iii., and 1 c.c. of pituitrin. It is given slowly during the course of the operation, about Oss. should be given at once, and the rest withheld until towards the end.

*Saline in the after-treatment.*—Rectal saline by intermittent small enemas 3 v. to 3 x. (with brandy 3 ii. to Oi. to promote absorption) is given as a routine measure for some days. Intravenous saline when a patient collapses after operation is useless, unless the collapse is due to secondary haemorrhage—which hardly ever occurs in abdominal cases.

*Incisions.*—The following are the chief points:—  
1. Where the location of the injury is uncertain and small intestine is almost certainly concerned a long (6-inch)

middle-line incision extending above and below the umbilicus is best. It should be made to one side of, and not through, the linea alba.

2. Where the injury can be localised to one side of the abdomen and there is a likelihood of colon being affected, either a vertical incision through the rectus sheath should be used (as has been done most frequently by us) or a transverse incision through the oblique muscles and extending into the rectus sheath (that muscle being pulled inwards) may be adopted.

3. Where injury to the flexures of the colon or the spleen is suspected a paracostal incision through the muscles, if necessary extended in the same way into the rectus sheath, has been frequently done, gives good exposure and heals well.

4. Sometimes where a primary lumbar incision has been made to deal with a wounded kidney and the missile not being found the immunity of the peritoneal contents is doubted, it is useful to remember that the peritoneum can be opened and often explored, sufficiently at least to establish the point, through the lumbar region.

Whenever possible the incision should be made separate from the original wound (in the case of large wounds only is this impracticable as a rule) and closed completely to obtain first-intention healing, drainage-tubes being inserted through separate button-hole incisions. Often the original wound can be utilised for a drainage-tube. It is wise to excise the skin around the original wound and to cleanse and drain with care large ramifying wounds in the abdominal wall. Gas gangrene does occur in these cases and is very fatal. On the other hand, with a separate operation wound it is surprising what good first-intention healing is usually obtained despite sepsis elsewhere.

*Closing the wound.*—The greatest possible care should be devoted to this. It is a point upon which we would lay most especial emphasis. A disconcertingly large number of these wounds have given way, often a fortnight after operation. Do not allow any consideration of time to prevent a careful closure in layers. The patient can be allowed to come round from the anaesthetic directly the peritoneum is closed and it is not this part of the operation which gives rise to shock.

We have abandoned entirely the use of a single row of deep sutures except in the most desperate cases, but use deep sutures in addition frequently. They should be of very strong silkworm-gut, set well back from the edge of the wound and not tied too tight, while they should not be removed till the twelfth day. In practically all cases the abdominal wall should be carefully sutured in layers. We generally use chromic gut, but silk is safer for the peritoneum.

The subject of importance of care in this matter may seem to be laboured, but when it is realised that the incisions are larger and owing to frequent bronchitis and paralytic distension the sutures are subject to a greater strain than is ever the case in civilian abdominal surgery, it will be understood that this is a point where technique is specially to be considered, and that even where everything possible has been done disasters will occur which will suddenly impose upon the patient a second operation and may imperil his chances of recovery. Of course, the danger is chiefly from middle-line incisions in the lower abdomen, but unfortunately these cannot be avoided in many cases.

#### *Examination of Abdominal Contents.*

In those cases where the damaged area cannot be localised—either by the existence of a through-and-through wound or the finding of the missile—a more or less complete examination of the abdomen is necessary. Both to save time and shock it is desirable that this should be done in an orderly routine way. Even then it occupies a large fraction of the total time for the operation.

Several surgeons engaged in this work examine the small intestine first and deal with it before turning to the other injuries. We prefer to examine the whole injured area, and when possible find or trace the missile before starting any repairs. There is one trifling advantage in this, and that is that in a desperate case which has been undertaken as a forlorn hope it may be found that, for example, suture of the stomach, colostomy, and a double resection of a small intestine would be necessary, it being manifest that the man will die on the table if this is attempted; the abdomen is closed and

the patient sent back to the ward as inoperable, morphia being given at intervals until death occurs. If the method of dealing first with the small intestine is used, the surgeon will be led to a procedure which involves a death on the table and wastes time when several patients may be waiting. There is one exception to the rule, and that is where a leaking large intestine wound is disclosed at once. It should, of course, be cleaned and repaired forthwith to avoid contamination during the subsequent examination.

We conduct the routine examination as follows. When the middle-line incision usual in such cases is used, the cæcum is first felt and seen if possible, then the termination of the ileum is identified, and the small intestine brought out and examined in short lengths of a foot or so, the uninjured gut being rapidly returned by the assistant. The advantage of beginning with the ileum is that wounds are rather more frequent than in the jejunum. When a rent is discovered, the wounded portion is retained outside the abdomen, the position of the first rent or hole being marked by a light clamp or otherwise. If a large portion has to be kept out in this way, it is, of course, covered by hot towels with saline. The small intestines being examined, the transverse colon and sigmoid may be largely seen, while the flexures, rectum, and bladder have to be felt, but it is surprising how readily a hole or tear can be detected in this way. In some cases the missile will be found loose in the pouch of Douglas, and it should always be looked for at this site if not found elsewhere.

#### *Wounds of Upper Viscera.*

In cases where the upper viscera are wounded the following points should be borne in mind.

*Stomach wounds.*—The stomach may be distended and yet a considerable hole or tear be present. If one hole only is found a second should always be looked for unless the missile is found in the stomach.

*Liver wounds.*—As has been said elsewhere, we do not operate on a case where this is the only lesion. If the wound in the liver is small and not bleeding it should be left alone. If large and inclined to bleed it may be packed. Suture is seldom possible, though it has been done successfully by one of us.

*Spleen wounds.*—If very small and not bleeding they may be neglected, but bleeding is usually going on or is at once started by manipulation. Moderate-sized tears are sutured or packed. Suture is easier than in the liver. We have reserved splenectomy for the most serious cases.

*Kidney wounds.*—It is as well to remember that although many kidney wounds can be detected by palpation through the peritoneum if the abdomen is open, yet there may be serious laceration concealed by a haematoma. In all cases where a kidney, as well as the abdominal contents, was affected, we have dealt with the kidney through a separate lumbar incision. It is seldom possible to diagnose the extent of its injury otherwise, and for this reason one is never tempted to try a transperitoneal nephrectomy to save a second incision. As to whether to suture, pack, or remove the kidney, we have only done the latter where the tear extended right across the hilum and haemorrhage was going on. In several cases an isolated portion of cortex of considerable size has been removed and the large gap sutured together with successful results.

#### *Wounds of Intestines and Bladder.*

As to the remaining viscera—intestines and bladder—the following are the results of our experience as regards technique.

*Small intestine.*—Where the holes are small a single row of Lembert's sutures or a purse-string is all that is necessary; double suture is only necessary for large tears which might bleed.

*Resections.*—The mortality of resection is nearly double that of simple suture, consequently wherever possible suture should be employed and resection should seldom be undertaken merely to save time. We have resected as much as 7½ feet successfully, and, curiously enough, these large resections seem to recover as well as much less extensive ones. It is as well to remember in such cases, where time is of particular value, that very large loops of mesentery may be taken up in each ligature if it be of stout silk and carefully tied.

We have generally done end-to-end anastomosis. Lateral anastomosis has been recommended strongly as giving

greater freedom from paralytic distension and obstructive symptoms afterwards. One of us has tried it in a number of cases. In our opinion there was nothing in the result to justify us in giving it any preference, and there is no doubt that it takes at least a quarter of an hour longer. In many very bad cases the end-to-end anastomosis has necessarily been done very hurriedly, but we have had no single case in which post-mortem examination failed to show a satisfactory union. Time should not be wasted in over-elaborate stitching in these anastomoses—we have seen a sufficient number to say with some confidence that the "leak" at the mesenteric attachment is a surgical "bogey."

Again, with a view to avoiding the effects of the supposed paralysis at the site of anastomosis or suture it has been suggested that where practicable the injured and repaired gut should be short-circuited. We have not done this, as our experience from post-mortem examination is that the paralysis is general, the result of peritonitis, and not limited to the injured area. Moreover, when account is taken of the fact that they are more serious cases, it is not more frequently associated with anastomosis than suture.

*Large intestine wounds.*—These are nearly twice as fatal as those of the small gut. Moreover, after their suture faecal fistula is only too frequent. The greatest care should be given to the suturing which, of course, is much more difficult than the small intestine; a double row of sutures should invariably be used and the gut should be carefully cleansed with antisepsics after the first is inserted. In addition a piece of omentum may be stitched over the repair. It may be necessary to make a separate "gridiron" incision in the flank to deal satisfactorily with ascending or descending colon wounds.

An important question which often arises is, Should one do a colostomy or not? When time is valuable and suture difficult one is tempted to bring the injured gut to the surface with or without a Paul's tube. Our advice is, never do so if suture can possibly be undertaken. The operation is a totally different one from a "civilian" colostomy, in which the gut is either left unopened or a Paul's tube firmly tied in at the highest point. In these cases there is already severe peritoneal infection and it is never possible to get a Paul's tube in really satisfactorily, so that the colostomy acts as a continual source of infection. Even if faecal fistula is inevitable, suture, when it can be done, closes the source of infection for some time. It will be seen how high the mortality of our colostomies has been, and we now regard it entirely as an operation of pure necessity where suture is impossible.

*Wounds of the bladder.*—Where there is an intraperitoneal wound only and this can be sutured, is it safe to do this without drainage of the bladder? We consider that it is, and have found that the result is just as satisfactory when the bladder is completely closed as when it is drained supravaginally. A catheter should be tied in, and, of course, in all bladder cases the pouch of Douglas is drained. Cases in which the missile has passed through the buttock and there is an extraperitoneal bladder wound which cannot be sutured are, like most buttock wounds, specially serious. The buttock is, of course, thoroughly drained, and, in addition, a tube can often be inserted outside the peritoneum and down into the space at the side of the bladder close to the wound in that organ. When such cases can be efficiently drained in this way they do well as a rule. In all wounds of the urinary tract hexamidine should be given from the start of the treatment until all danger of sepsis is past.

*Drainage of the abdomen after operation.*—In every case where there has been escape of visceral contents we drain the pouch of Douglas. In cases where there has been no escape of contents, and, for example, a foreign body has been removed from the peritoneum only, a local drain is quite sufficient; we have found it inadvisable to disengage with it, though this has been done quite successfully. When a drainage-tube is near or in contact with a sutured large intestine wound it should be removed on the second day, as it may encourage a faecal fistula. Speaking generally, we find it quite unnecessary to retain any drainage-tubes for long—their purpose is served once a channel is formed.

#### After-treatment.

The subject of salines here has already been dealt with. Fowler's position is, of course, the rule. One of the most

disappointing phenomena in these cases is the occurrence of a rapid collapse 12 to 24 hours after operation in a patient who has apparently rallied well from the primary shock. It is hardly likely that the condition is due to toxæmia from incipient peritonitis, and post mortem nothing has been found to account for it. The condition is best described as "secondary shock," but while it accounts for many deaths, is not easily explained or treated. Intravenous saline is useless; stimulants (strychnine and brandy) appear sometimes to have accounted for a second rally.

It is possible that the collapse represents the result of operating on a patient with too great a degree of primary shock—it is certain that it occurs in those with most well-marked shock at first—but since in so many patients of this class the chances without operation are almost nil, this view does not help one much. We believe, however, that secondary shock can be prevented, to some extent, by a short delay to warm and rest patients who come in a bad condition.

Most patients vomit at intervals on the day after operation and, speaking generally, these patients are more troubled by vomiting than "civilian" acute abdominal cases. Fluid should be resolutely withheld, despite the intense thirst, when this vomiting shows no sign of ceasing early; often 12 hours without anything by the mouth will stop it. In some such cases there is acute distension of the stomach, and where this is unmistakable a stomach tube has cured the condition, but it should not be used in a collapsed patient.

The rest of the after-treatment is devoted to aiding the patient's combat with his peritoneal infection, and while almost every one has, presumably, some degree of peritonitis it is surprising how comparatively infrequent ordinary general peritonitis is. The chief danger to a man shot in the abdomen when he can be operated on in reasonable time is not peritonitis, but shock and haemorrhage. If these two could be entirely eliminated, it is safe to say that the total mortality would be reduced by 30 or 40 per cent.

The chief symptoms from supervening peritonitis are paralytic distension, vomiting, and constipation. There is, of course, a primary paralysis of the intestine after the wound, and in cases with little peritonitis this passes off in the first 24 hours. When, however, the paralysis due to peritonitis is superadded we get an exaggeration of these symptoms which in bad cases passes on in time to real obstruction. Fortunately, many cases stop short of this and yield to medical treatment.

As a prophylactic one of us gives hypodermic pituitrin, followed in half an hour by an enema on the day after operation. All of us agree as to the importance of getting the bowels open upon the third day if possible. When obstructive symptoms with paralytic distension threaten, one of the most valuable drugs is hypodermic eserine, gr.  $\frac{1}{15}$ , being given every two hours. Small doses of calomel, hypodermic pituitrin, and turpentine enemas are also used.

In cases where this fails and real obstructive symptoms come on, post-mortem examination usually reveals a condition of general peritonitis, with pockets of pus, adhesions, and often multiple kinks. The patients are usually desperately ill by the time such a condition is established, and the chance of doing anything by operation is not hopeful. Perhaps the best plan is to open up the wound and to search gently with the finger for any collection of pus, separating any adhesions close to the wound; this can sometimes be done without an anaesthetic, and we have had more than one case in which it appeared to save life, but, unfortunately, many more in which it failed. It has been suggested that a distended coil of gut should be drained by suturing in a small tube; we have tried this so far unsuccessfully, and the fact that points of obstruction are so often multiple does not render it very hopeful.

Tubes, as has been said, are removed early. Where gauze packing is used—in a liver or spleen—it is wisest to leave it alone for four days, and then if difficulty is encountered an anaesthetic is often avoided by removing it by stages.

Lastly, we would emphasise the fact, which experience has shown, that these patients are often a good deal upset by the journey to the base, and on no account should a patient be sent earlier than can be avoided or before the end of a week, however well he is. Most of our patients leave for the base in between 10 days and a fortnight.

TABLE I.—Mortality Results of First 500 Operations.  
Total: 245 lived, 255 died. Recovery-rate, 49 per cent.

Class.	Nature of visceral injury.	Total No.	Result.		Recovery rate, per cent.
			Lived.	Died.	
1	Stomach—No other injury .. .. .. .. ..	9	6	3	66·6
	" All stomach wounds .. .. .. .. ..	23	8	15	34·7
2	Small intestine—Sutured; no other injury ..	64	40	24	62·5
	" " all cases .. .. .. .. ..	96	53	43	52·2
	" " Resections alone .. .. .. .. ..	58	18	40	31·0
	" " " all cases .. .. .. .. ..	90	26	64	23·8
3	Large intestine—Sutured; no other injury ..	45	21	24	48·8
	" " all cases .. .. .. .. ..	119	43	76	38·1
	" " Colostomy .. .. .. .. ..	13	2	11	15·3
4	Liver—Pure liver wounds .. .. .. .. ..	27	13	14	48·1
	" All .. .. .. .. ..	58	19	39	32·7
5	Spleen—No other injury .. .. .. .. ..	11	6	5	54·5
	" All cases .. .. .. .. ..	17	8	9	47·0
6	Kidney—Pure kidney wounds .. .. .. .. ..	10	6	4	60·0
	" All cases .. .. .. .. ..	20	12	8	60·0
	" Nephrectomies .. .. .. .. ..	2	2	0	100·0

	" All cases .. .. .. .. ..	9	5	4	55·5
9	Laparotomy—(a) With no injury found .. .. ..	57	53	4	92·9
	(b) Retropertitoneal haematomata only .. .. ..	23	9	14	39·13
	(c) Bruising of intestine and haemorrhage .. .. ..	9	7	2	77·7
10	Cases in which peritoneum was opened by original wound but no visceral injury .. .. .. .. ..	10	6	4	60·0
11	Cases with protrusion of intestine† .. .. .. .. ..	16	6	10	37·5
	" " " " uninjured .. .. .. .. ..	5	3	2	60·0
12	Wounds of chest and abdomen‡ .. .. .. .. ..	27	5	22	18·5
13	Gas gangrene of abdominal wall .. .. .. .. ..	11	1	10	9·0

\* All these cases had other wounds. None died from operation.

† Included in some cases under small intestine.

‡ These cases had wound of lung. All that recovered had only solid viscera injured in the abdomen.

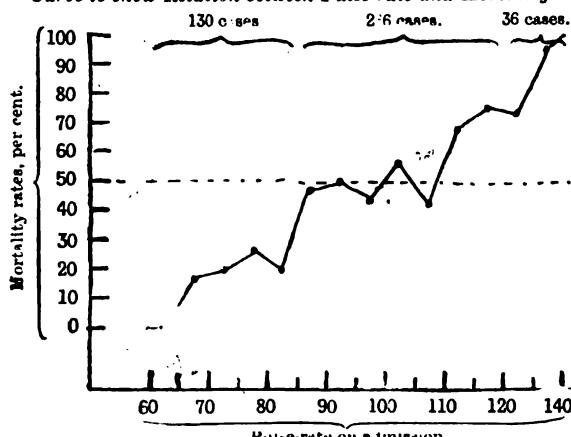

TABLE II.—Regional Mortality of 467 Cases.

	Lived.	Died.
Anterior abdominal wall .. .. .. .. ..	96	97
Flank or loin { Right .. .. .. .. ..	28	20
Left .. .. .. .. ..	34	29
Chest * { Right .. .. .. .. ..	26	25
Left .. .. .. .. ..	25	20
Buttock (either side) .. .. .. .. ..	18	49

\* I.e., wound above rib margin—not only wounds of lung, for mortality of which see Table I.

N.B.—In this table where there are through wounds with exit and entry in different regions the case is classified in the category standing lowest in above scale—i.e., "Anterior abdominal wall and buttock"—under "Buttock."

Curve to show Relation between Pulse-rate and Mortality.

Note on the foregoing Tables and Chart.

Table I.—The whole paper forms a commentary on this table. Note especially the high mortality of colostomy,

retroperitoneal haematomas, gas gangrene of abdominal wall, and wounds of lung and abdomen. It is especially significant that our only recoveries in the latter cases were wounds of solid viscera where expectant treatment might have sufficed.

Table II.—Here the cases are classified according to region wounded. The chief value of this lies in bringing out the high mortality of buttock wounds. Many of these cases had slight visceral injuries. Death is due to haemorrhage and sepsis in the buttock and to pelvic cellulitis. Wounds of loin and flank and chest wall include most of the solid viscera wounds and most where nothing was found on operation, hence their mortality below the average.

Pulse chart.—This shows very clearly that when the pulse is between 85 and 110 the prognosis is that of the average—about 50 per cent—and there is little to choose between these rates. Below 85 prognosis is very good and above 110 very bad. In preparing this table it was noticeable that most fatal cases with low pulse-rate were buttock cases or died of other wounds.

#### Conclusion.

All statistics are full of fallacies, and none more so than the mortality rates of different series of these cases. As will be seen, wounds of a single viscera are in a small minority. Cases comparable as regards the abdominal condition are often differentiated entirely by some severe complication in the nature of a wound elsewhere. Comparatively slight abdominal cases develop perhaps gas gangrene or bronchitis and pneumonia, while the most serious may, in contrast, have no other wound and every condition in his favour. Mental shock and exhaustion and fear are noticeable factors in a patient's course, and at one time we had a number of cases who had been in addition poisoned to varying degrees by gas shells.

Any attempt at exact statistical comparisons will require an enormous series of cases. All one can say at present is that if large numbers are taken about half survive after operation. The mortality of all cases is a much more difficult matter, since in those which recover without operation it is often impossible to say whether the abdominal cavity was penetrated or not.

In the heavy work with the main Somme fighting we kept no careful notes of these, and so we refrain from publishing figures which might be misleading, but we would state emphatically from the consideration of a small series recently worked out carefully with the aid of a sectional atlas that there have been many recoveries from wounds of the hollow viscera without operation.

We have made no attempt to present the individual cases appertaining to each of us separately; but, as a matter of fact, the mortality rate of each operator's series works out at very nearly the same figure. It is essentially in the diagnosis and selection of these cases rather than in the technique of operating that experience is of such value, and it is here that one feels that one continues to make definite progress as it increases.

Not many series of abdominal cases have as yet been published, and none that we are aware of so large as this, and we would emphasize the futility of attempting comparisons of small series as to "results." In each of our individual series a portion of 30 or 40 consecutive cases can be picked out which shows either an extremely low or an appallingly high mortality. It has happened to one of us to get a dozen consecutive cases which have lived, and to another as many in succession that have died. Two surgeons of equal merit and experience may differ in the extent to which they will go in operating upon the "forlorn hope" type of case—a difference which will show itself in statistics.

So that our final word on statistics is that no surgeon should let himself be troubled by them or allow any consideration for them to influence his judgment in an individual case. The vast majority of the patients who die, die in the first 24 hours from shock and haemorrhage. There is only one really outstanding problem in the matter, and that is the enormously difficult one of the nature and treatment of shock. Its solution, which can hardly be expected in this war, will alone make any dramatic and striking difference in the death rate of these cases.

The last point to touch on is as to the fate of the cases who leave us for the base and are marked "lived" in these tables. Owing to a system in use since July we send each patient down with a card, which is returned to us from the base with an account of him, while later we hear from

England as to the final result. Sufficient of these returns are not yet in to include them in our table, but we can say confidently that the number who die after they leave us is very small, certainly well under 5 per cent., while we already know of several who are fit for duty.

Taking it upon the whole, recovery, if death does not take place in the first few days, is better after these abdominal wounds than after the severest type of head, chest, or limb wounds. It is likely that some of our patients will have some lengthy disorders of digestion or nutrition. Cases of large resections seem especially likely to do so; one imagines that adhesions and ventral hernia will frequently require attention for some time to come.

In final conclusion we apologise for shortcomings in the writing of this paper by pointing out that it has been written and the facts and statistics collected in short intervals of leisure "in the field."

## A Lecture ON THE TREATMENT OF SECONDARY HÆMORRHAGE, WITH SPECIAL REFERENCE TO GUNSHOT WOUNDS.

*Delivered in the University of Bristol in the Autumn Session, 1916,*

BY CHARLES A. MORTON, F.R.C.S. ENG.,  
PROFESSOR OF SURGERY IN THE UNIVERSITY; SENIOR SURGEON TO THE GENERAL HOSPITAL AND THE CHILDREN'S HOSPITAL; CONSULTING SURGEON TO THE CHESTNUT HOSPITAL; ACTING SURGEON TO THE BEAUMONT WAR HOSPITAL, BRISTOL.

GENTLEMEN.—In surgical practice in civil life secondary haemorrhage is of rare occurrence, but in connexion with the large number of suppurating gunshot wounds with which we have to deal at the present time it is quite common, and as it is necessary to have a very clear idea in our mind as to how a case, which may be one of extreme urgency, should be treated, it is worth while considering the subject at some length.

### THE NATURE OF THE HÆMORRHAGE.

Secondary haemorrhage is always due to a failure by nature to occlude permanently an injured vessel, and in the great majority of cases an injured artery. It does not usually occur before the second week after the injury, but may occur earlier. I have had a case myself of secondary haemorrhage from the anterior tibial artery in a suppurating compound fracture as early as the fourth day. It must be clearly distinguished from what is called reactionary or recurrent haemorrhage, which occurs some hours after an injury or operation, and may be due to increased force of the circulation restarting the haemorrhage or to slipping of a ligature. Secondary haemorrhage almost always occurs in suppurating wounds; a great number of such wounds, complicated by the occurrence of secondary haemorrhage, at the military hospital are compound fractures.

In order that you may understand how best to deal with it, it is very important that you should have a clear idea of its nature. It may start as quite an insignificant bleeding. Perhaps the nurse may tell you that when she removed the dressing she found a few clots of blood in it, but that the bleeding had quite ceased. Now if a large artery is known to have been injured, or even if the wound track runs in the neighbourhood of a large artery, this is a very serious occurrence. You must always impress on nurses that they should at once report any bleeding from a wound, however trivial it may seem. With no more bleeding than this I have opened up a suppurating gunshot wound of the leg and found an opening in the posterior tibial artery. If once secondary haemorrhage has occurred from an injured artery it is almost certain to recur, and any recurrence may be so severe as to be fatal.

It may be well to consider what may cause bleeding from a wound, in the second week, besides injury of an artery. Of course, if granulation tissue, which is very vascular, is probed or otherwise injured, it will probably bleed; but, apart from any injury, it is stated in some of the text-

books that granulation tissue may bleed, and what is described as "parenchymatous oozing" is said to occur from sloughing wounds, and to be apt to recur, and ultimately to prove fatal. I have had one case of suppurating compound fracture in which bleeding took place twice within 24 hours, and as the wound was close to a main artery I opened it up and found it full of clot. But I could not find any bleeding vessel, only small areas of bleeding granulation tissue, and after cleaning out the wound I packed it with gauze saturated with turpentine, as advocated by Mr. Grey Turner, of Newcastle,<sup>1</sup> and no recurrence of the haemorrhage took place.

In another case in which there had been recurrent attacks of haemorrhage for a fortnight before I saw the patient and he had become quite anaemic, when I opened up the wound, which was close to the popliteal space, the only bleeding vessel I could find was a venous branch. This I tied, and there was no further bleeding. In a case of very smart secondary haemorrhage from a gunshot wound of the calf, in which from the position of the wound track one of the main arteries of the leg might have been wounded, I found the bleeding was from an arterial muscular branch.

### TREATMENT OF SECONDARY HÆMORRHAGE FROM A VESSEL IN CONTINUITY.

I will first describe how I think secondary haemorrhage should be treated, and then refer to the recommendations of other surgeons as to other methods, and I will consider first secondary haemorrhage from a vessel in continuity, and later secondary haemorrhage from stumps. You must clearly recognise that even if the bleeding has ceased, and however slight it may have been, something must be done if it is known that a main artery is injured, or even if from the proximity of the wound to such a vessel it seems probable that it is, and I think the only really safe way of dealing with such a condition is, as soon as possible, to cut down on the bleeding vessel and tie it. I say as soon as possible, because although the first haemorrhage may be quite slight a second may be fatal, and this may come on at any time.<sup>2</sup>

You will remember that in dealing with primary haemorrhage it is always wise to tie at the bleeding spot, and to tie both ends of a divided artery. Proximal ligation is not to be recommended, for it may not be the main artery which is wounded but only a branch, and it would not therefore be necessary to tie the main artery at all, and if you perform proximal ligation as soon as the collateral circulation begins to form blood is brought to the distal end and haemorrhage may recur; a d, moreover, if you tie the vessel some distance above the point where it will be occluded in the wound, you get a double block in the artery, and, in the lower limb at any rate, run a risk of causing gangrene. For these reasons you should whenever possible open up the wound track and find the bleeding vessel and tie it, and, as in the case of primary hemorrhage, you should always tie an artery both below as well as above the opening into it to prevent bleeding from the distal end when the collateral circulation becomes established. You will not always find the bleeding is from a main artery, as I have already said, but the chances are so great that it will be from such a source if the wound track runs in the neighbourhood of a large artery, that it is certainly wise to act as if we knew the bleeding came from a main artery.

But there are a few situations in which you cannot reach the artery, and sometimes when you open up the wound the bleeding artery is surrounded by such sloughy tissue no ligature would hold. In such circumstances you are obliged to perform proximal ligation. I have had to ligature the external carotid for secondary haemorrhage from a branch of the internal maxillary artery. But proximal ligation is to be avoided if you tie at the bleeding spot. It may be much easier to perform proximal ligation than to tie at the bleeding spot in a deep wound, but it is not good surgery. I have just stated that the wound may be too sloughy to tie the artery at the seat of bleeding. But you must recognise that the vessel may be surrounded by soft granulation tissue, and

<sup>1</sup> THE LANCET, 1915, II., 226.

<sup>2</sup> Sir G. R. Makins (British Journal of Surgery, January, 1916, p. 347) has pointed out that in cases of traumatic aneurysm, if slight bleeding occurs from the external wound during the first few days after the wound is inflicted, no operative measures are required, for this slight and early haemorrhage may be simply an escape of blood from what he calls the "arterial hematoma."

it may not appear possible to tie it at the bleeding spot, and yet if you scrape away the soft tissue with the blunt end of the scalpel you may find that you can expose the artery where it will take a ligature. In some cases a ligature may be passed around the artery and the surrounding soft tissues, or we may be able to catch the bleeding vessel together with some of the surrounding soft tissue in pressure forceps, and leave them on for 24 or 48 hours.

But having found and tied the bleeding vessel, we must do more than that—we must take measures to try to get the wound less septic, or secondary haemorrhage may even recur at the seat of ligature. At the time of ligation we must well clean out our wound with swabs, cut away all sloughs, and then apply for a very definite period of time (just douching the wound is not enough) a strong antiseptic such as eusol. But it would be much better to apply the antiseptic continuously for some days, either by constant irrigation or by Carrel's method.

#### *Immediate Treatment.*

I must now say something about the immediate treatment of secondary haemorrhage—what we may call first-aid treatment. Every military surgical ward should have a rubber tube tourniquet readily available, and the nurse or orderly should be instructed how to make a tourniquet out of something certain to be at hand if the actual tourniquet was not, and they should also be instructed that it must be put on tight enough to occlude the arteries and not so as merely to cause venous congestion, and so increase rather than stop the haemorrhage. If the haemorrhage was not very great it would be better for the nurse or orderly to call medical aid, so that the tourniquet might with greater certainty be applied effectually.

If operation cannot at once be performed the patient should have a hypodermic injection of morphia, for the pressure of the tourniquet round the limb may cause much distress. It should be left on until the patient is under the anaesthetic and the wound opened up; then it should be released, but only so that, if necessary, it can be instantly reapplied. When it is released the vessel will very likely bleed and can be secured, but it may not; but even then we may find an opening into an artery by careful search in the wound. We may perhaps start the bleeding by rubbing over the wound surface with a swab and so detach some clot which is temporarily stopping the opening in the vessel. If we cannot find any injured vessel we shall have to be content with very firm packing of the wound with gauze saturated with turpentine and watch the case with great care for any recurrence of the bleeding. If serious bleeding did recur and a second attempt to find the bleeding vessel failed I suppose we should have to resort to proximal ligation of the main artery supplying the region of the wound.

#### *Secondary Haemorrhage Not Controllable by Pressure on Proximal Vessel: Groin and Gluteal Region.*

But there are some regions in which secondary haemorrhage from a large artery may take place, but the haemorrhage cannot be controlled by a tourniquet or even by digital pressure on a proximal main artery. The root of the neck, the groin, and the gluteal region are such areas.<sup>3</sup> In these regions immediate pressure in the wound must be made, and all nurses employed in military surgical wards should be instructed how to employ it. The wound or wounds from which the haemorrhage comes must be tightly packed with gauze, as far as it is possible to get a gauze plug into some of these gunshot-wound tracks, and digital pressure kept up on the gauze plug where it projects from the wound until the haemorrhage has ceased, or if it can only be controlled by keeping up such pressure, it must be kept up until the patient is under the anaesthetic and the surgeon is ready to open up the wound.

In the case of the groin or gluteal region, if the haemorrhage has been severe it is a question whether it will be safe to remove the plug without first obtaining control over the main supplying artery. For when we remove the plug the haemorrhage may again be severe, and no tourniquet can be applied to control it while we search for the injured vessel. It seems to me that we should make the attempt—i.e., we

should remove the plug and see if violent haemorrhage will recur. If it does not, we can safely open up the wound and search for the bleeding vessel. If it does, it would be almost impossible to do so in a deep wound converted into a pool of blood, and we should have to plug again at once. We must then ligate the main artery through the abdomen, the external iliac in the case of a groin wound, and the internal iliac in the case of a gluteal wound. An alternative method would be the application of Crile's clamp to the artery, so that it would not be permanently occluded at this spot, but the objection to this method would be that we should have again to open the abdomen to remove it after dealing with the septic wound. But there would be no risk in doing this if adequate precautions were taken in changing gloves, towels, &c., and resterilising instruments, and it would be a great advantage to avoid the risk to the circulation of the limb of proximal ligation.

Having thus controlled the main vessel we should, after closing the abdominal wound and applying an aseptic dressing to it and covering this over with some waterproof material, then search for the bleeding vessel in the gunshot wound and tie it there. We should not be content with proximal ligation, which has really only been used as a substitute for the application of a tourniquet, because the bleeding may recur from the distal end of the injured artery if we do not tie it at the bleeding spot and tie both ends.

#### *The Root of the Neck.*

In the neck, of course, haemorrhage can be controlled from the external or internal carotid, or the region of the bifurcation of the carotid, by digital pressure on the common carotid, but we may have to deal with secondary haemorrhage at the root of the neck. If it has not ceased when we operate it must be controlled by digital pressure in the wound. There would be no room for a gauze plug because we have to control the proximal artery so close to the bleeding spot. In secondary haemorrhage from the third part of the subclavian we might be able to tie the first part without resection of the clavicle, but when the haemorrhage is from a vessel on the inside of the scalenus anticus it might be necessary to resect the inner part of the clavicle so as to get at the artery on the proximal side in order to control the circulation in it while we dealt with the bleeding spot in the vessel; for if the bleeding had not ceased at the time of the operation but had to be controlled by digital pressure in the wound, if the bleeding vessel were a main artery it would only be possible to tie it after control of the proximal trunk. If the bleeding was coming from the thyroid axis or one of its branches or the vertebral artery it might be possible to pick it up and tie it, after a free exposure of the area. But after digital pressure had been removed I do not think hemorrhage from a main artery could be effectively dealt with until the proximal vessel was controlled.<sup>4</sup>

Of course, in some desperate cases, as in wounds in a region, space is so limited for access to the vessels, and with the parts infiltrated with blood and perhaps sloughing, it may be that the only thing we may be able to do is to maintain firm plug pressure. In making such pressure I would suggest that an elastic bandage should be carried over the root of the neck and under the axilla of the opposite side, and then

<sup>4</sup> In some of these desperate cases of secondary haemorrhage on the inner side of the root of the neck, or if a large vein were wounded behind the inner end of the clavicle in the removal of malignant glands in this situation, it has seemed to me that removal of the inner end of the first rib, together with the corner of the sternum to which it is attached (as well as the inner end of the clavicle), might enable the surgeon to secure the bleeding vessel when it would not otherwise be possible. But this procedure would involve a risk of wounding the internal mammary artery which lies just behind the cartilage of the first rib. The best plan would be, after removal of the inner end of the clavicle, to catch the artery in forceps as it was passing downwards to lie behind the cartilage of the first rib. It would be necessary also to protect the structure lying beneath this corner of the sternum and the inner end of the first rib with a metal spatula when dividing the bone, and it would be necessary not only to detach the sterno-mastoid and pectoralis major from the front but the sterno-hyoid and thyroid would have to be separated from the posterior aspect of the corner of the sternum. A very interesting case of ligation of the first part of the subclavian artery for secondary haemorrhage is recorded by Victor Bonney (Brit. Med. Jour., 1916, 1, 754). He was able to tie the artery at its junction with the innominate artery after resection of the inner end of the clavicle by making traction on it, and he advocates such traction as a means of reaching these deep vessels. He says in his case, as in others, the upper end of the innominate artery and the root of the subclavian lay well behind the manubrium sterni. Fortunately, in his case bleeding had ceased before the operation was performed.

<sup>3</sup> I have not included the axilla with the regions referred to, because it would be possible to control the third part of the subclavian artery by digital pressure, but it would be much safer to expose it, and apply to it a Crile's clamp.

the axillary loop should be kept well down in the axilla by a bandage carried through it and round the perineum.

*Conditions Found on Operating.*

It may be interesting to consider exactly what conditions we are likely to find when we open up the wound to deal with the bleeding. In nearly all my cases the hæmorrhage was found to be coming from a wholly or partly divided artery, and in most cases a main artery, though in one case it was from the peroneal in the lower part of the leg, and in another from only a muscular branch, though in this case the hemorrhage was quite smart. I have already referred to a case in which the hæmorrhage had been recurring at frequent intervals for a fortnight and the patient had become seriously anaemic before I saw him, yet the hemorrhage was only from a vein and it was quite stopped by its ligation. These three cases well illustrate how unwise it would be to tie the main vessel on the proximal side. If I had done so I should have tied the popliteal artery in one of the cases and the superficial femoral in another without any need.

My experience in these military cases has taught me the interesting fact that an artery such as the ulnar or posterior tibial may be very freely opened in a gunshot wound and may be found open and bleeding as late as the fourteenth day, and yet except for some hemorrhage at the time of the injury no hæmorrhage has occurred until the fourteenth day. It seems likely that the opening in the vessel is plugged by clot, and that eventually that clot is disturbed or dissolved, but there is no apparent reason why this should take place at the particular period when it does. The hæmorrhage in these cases is not associated with movement of or by the patient. And another interesting question is, Why does the bleeding spontaneously cease, as it certainly may, even if severe? You may open up the wound and find a considerable-sized opening or a complete division of the artery, and yet the hæmorrhage, which may have been severe, has ceased. Of course, when a patient becomes collapsed from loss of blood hæmorrhage very often ceases, but this condition was not present in the cases I refer to.

I should like again to call your attention to the fact that sometimes you may get marked hæmorrhage from a suppurating gunshot track in the neighbourhood of a large artery, and yet when you open up the wound, though you find it full of clot, you may fail to find, even after the most thorough search, a definite bleeding vessel, but the blood is coming from certain areas of granulation tissue. I had such an experience in the case of gunshot fracture of the upper end of the humerus (and I have already briefly referred to the case), where the wound track ran close to the brachial artery, and when it was opened up it was found full of clot. The best plan in such a case is to clean out the wound, and then to pack it tightly with gauze saturated with turpentine.<sup>5</sup> This may stop such hemorrhage.

In some cases in which you have to operate for secondary hæmorrhage you may find the opening in the artery communicates with a collection of old clot in a cavity in the tissues (a traumatic aneurysm) and yet there is an external wound, and through that wound hæmorrhage may occur as late as the fourteenth day. I have met with this condition in connexion with a gunshot wound of the posterior tibial artery; and in the case of a boy I operated on in civil practice frequently recurring hæmorrhage took place from a punctured wound of the sole of the foot. At the operation I found a cavity in the tissues containing old firm clot, and with this, through a minute puncture, the external plantar artery communicated. Recurrent bleeding took place through a sinus in the sole as late as a month after the injury. In another case in which I had to operate for secondary hæmorrhage (also in civil practice), associated with a septic compound fracture of the tibia, I found a small aneurysmal sac, almost the size of a pea, on the anterior tibial artery, and this sac had perforated. Its wall was white and very soft, and evidently due to septic change in the vessel wall. The hemorrhage occurred as early as four days after the injury.

*Other Methods of Treatment.*

I have described the method of treatment which I think should be adopted in cases of secondary hæmorrhage, but I should like to call attention to other methods which are advocated. One method which is recommended in one of the text-books of surgery is plugging the wound. It is said

that if the hæmorrhage is not severe and does not come from a large artery, it may be treated by packing the wound firmly with gauze. But how are we to know that it does not come from a large artery if the wound track is anywhere in the neighbourhood of one, and even if the more superficial part of the wound track is not near a large artery yet such tracks are often very long and complicated and may extend much farther than we may think. No doubt in many cases in which we can pack the whole wound with gauze, especially if it is wrung out of turpentine, this may stop the hæmorrhage, but there is danger of a very serious or even fatal recurrence of the hæmorrhage if a large artery has been wounded. But in many, probably in most, cases of secondary hæmorrhage in gunshot wounds the wound is not an open wound that can be packed to the bottom. I do not think in any of my own cases of secondary hæmorrhage the hæmorrhage could have been treated by packing the wound with gauze without first freely opening it up. I think all wounds complicated by secondary hæmorrhage I have had to deal with have been deep tracks. And if you have to give the patient an anaesthetic and open up the wound in order to pack it, clearly it would be better to search very thoroughly for a bleeding vessel in order that you may tie it. Even as a temporary measure, whenever it can be done, it would be safer to put on a tourniquet than to plug the wound—i.e., until operation could be performed; but, of course, in those positions in which no tourniquet could be used and the artery cannot be compressed on the proximal side plugging is the only temporary measure we can adopt. And if secondary hæmorrhage occurs in some locality where there is no possibility of performing an operation, such as during transit to hospital, and the wound is in such a position that no tourniquet could be applied, all we can do is to pack the wound with gauze, wrung out of turpentine, if that is available.

Another method of treating secondary hæmorrhage to which I must also refer is the combination of plugging of the wound with compression of the artery on the proximal side for some days by means of a screw tourniquet. But this is almost intolerable to the patient and would require frequent large hypodermic injections of morphia, and after causing much distress to the patient it might not be successful, or if it did prevent recurrence of the bleeding it might cause a thrombus to form in the artery at the seat of compression, and thus a double block in the vessel and in the lower limb, if not in the upper; this would involve a risk of gangrene. Moreover, this painful and somewhat risky process might be unnecessary, for it might not be a wound of the main vessel at all, but only of a branch which might be easily found and tied, if the wound were opened up.

It is sometimes recommended that after one secondary hæmorrhage a screw tourniquet should be applied over the main vessel, and the nurse should be instructed how to screw it down if the hæmorrhage recurs. But who would care to trust to such a method? Very likely, if it did recur, the tourniquet would have slipped off the artery, and the nurse would not know exactly the spot where the artery was lying, and therefore in screwing it down might not control the vessel at all. If this method were adopted the only safe way would be to put an indelible mark on the skin over the artery and instruct the nurse to screw down the tourniquet on that. But it is much safer not to trust to the nurse dealing with what may be a very severe recurrence of the bleeding, but to open up the wound and deal with the bleeding vessel.

**SECONDARY HÆMORRHAGE FROM STUMPS.**

I should like now to consider how secondary hæmorrhage from stumps should be treated. We have the two essential differences between the hæmorrhage from stumps and from an artery wounded in continuity, that in the former the risk of either bleeding from the distal end of the artery, or of gangrene of the limb, is not present, and if we tie the main vessel close to the stump this will stop bleeding from a branch, if it happens to be a branch which is bleeding, as well as from the end of the main vessel, unless that branch should come from the main artery above the seat of ligation. Such proximal ligation must be close to the stump, or we should get blood brought to the injured vessel by the establishment of the collateral circulation between the seat of ligation and the injured vessel.

Proximal ligation has great advantages. In the first place you can make an aseptic wound for your ligature, and in the second place you avoid disturbing the healing process in the stump. We could well treat in this way secondary haemorrhage from a sump in the lower part of the thigh, where the only large artery would be the superficial femoral or the popliteal. In the upper part of the thigh the bleeding might come from either the superficial femoral or the profunda, but if we tied the common femoral we should control both.

In the lower part of the leg the haemorrhage might come from any one of the three main arteries there, and we could hardly tie all three main vessels higher up in the leg, and so we should have to open up the stump and deal with the bleeding vessel there. In the upper part of the leg, however, we might quite well control bleeding from either of the three arteries by tying the popliteal just before its division.

In the upper arm, the only main artery being the brachial, we could well adopt proximal ligation, and in the forearm we could tie either the brachial at the bend of the elbow, or both forearm main arteries, according to the level of the amputation.

### TYPES OF TUBERCLE BACILLI IN CERVICAL AND AXILLARY GLAND TUBERCULOSIS.

BY A. STANLEY GRIFFITH, M.D.VICT., D.P.H.,  
LATE RESIDENT SCIENTIFIC INVESTIGATOR, ROYAL COMMISSION ON  
TUBERCULOSIS.

(For the Medical Research Committee.)

In continuation of my work on cervical gland tuberculosis, of which an account was published in THE LANCET in June, 1915, I have examined bacteriologically material from a further series of 52 persons suffering from enlarged cervical or axillary lymphatic glands. This additional material was obtained in order to bring up to 100 the total number of strains of tubercle bacilli isolated by me from cases of cervical gland tuberculosis. The desired number of strains was secured in May, 1916, and the experimental investigations in connexion therewith were completed in October, 1916.

In this communication I propose, first, to state the results obtained from investigation of these 52 new cases, and, finally, to summarise the whole of my observations upon the types of tubercle bacilli found in cervical gland tuberculosis.

For supplying me with the material and clinical particulars of the 52 cases I am much indebted to Colonel C. J. Bond, Leicester; Mr. H. J. Gauvin, Alton; Colonel J. Griffiths, Cambridge; Major R. E. Kelly, Liverpool; Dr. A. H. Miller and Miss M. S. Gordon, Manchester; Mr. F. C. Pybus, Newcastle; and Surgeon R. A. Rankine, R.N. The material has consisted of glands removed by surgical operation and pus aspirated from glandular abscesses or collected on the dressings of discharging neck sinuses. The methods of investigation have been the same as those described in my previous report.\*

The work was carried out in the Pathological Department of the Field Laboratories, University of Cambridge, on behalf of the Medical Research Committee.

#### I. Results of Investigation of Material from 52 Persons Suffering from Enlarged Lymphatic Glands.

##### (A) Cases which gave Negative Results.

The material from 17 of the 52 cases did not produce tuberculosis in guinea-pigs. In 4 of these negative cases the original material was pus or dressings from neck sinuses. In 6 cases the material consisted of enlarged cervical glands, which on section were either hyperplastic or contained purulent foci and were not definitely tuberculous; microscopic examinations and cultivation experiments in these 6 cases were likewise negative. In 7 of the 17 cases the material, enlarged cervical glands, was macroscopically tuberculous. The glands showed on section caseous-calcareous nodules and tubercles, and in 3 of the cases tubercle bacilli were found on microscopical examination. Direct cultures from each material remained sterile.

##### (B) Cases from which Tubercle Bacilli were Isolated in Culture.

The material from 35 cases produced tuberculosis in guinea-pigs and cultures of tubercle bacilli were isolated either directly from the original material or through the guinea-pig. The cultures are divided into three groups, composed respectively of (1) standard bovine, (2) standard human, and (3) atypical strains. The results obtained with each group of cultures are described separately. The clinical particulars and the result of the bacteriological examination of each of the 35 cases are set out in Table II.

##### (1) Standard Bovine Strains.

From 15 of the 35 cases cultures were obtained which produced in rabbits the pathogenic effects of standard bovine tubercle bacilli. All except one of these strains were dysgenic and exhibited the same range of variation of cultural characteristics as tubercle bacilli of bovine origin. The exceptional strain grew rather more luxuriantly (on glycerine egg and glycerine agar) than any strain which I have so far found in bovine tuberculous lesions, though not with the luxuriance of standard human strains. The eugenic character of this strain was not altered by passage through the body of the rabbit. None of the viruses was tested in culture on the guinea-pig, since the original material of each had produced typical tuberculosis in this species of animal.

The results in rabbits of the inoculation of the 15 strains of culture are briefly summarised in Table I. The rabbits

TABLE I.—Experiments on Rabbits with Virulent Strains.

No. of case.	No. of rabbit.	Dura-tion of life.	Result.

were inoculated subcutaneously between the shoulders, each with 10 mgm. of moist growth from young serum cultures. The initial weights of the rabbits ranged from 1200 to 2800 gm.

##### (2) Standard Human Strains.

From 19 viruses (18 cervical and 1 axillary gland) cultures were obtained which grew on serum and glycerinated media with the characteristic luxuriance of the human type of tubercle bacillus. The virulence of these 19 viruses was tested on the guinea-pig by the intraperitoneal inoculation

of original material, and on the rabbit by the subcutaneous inoculation of culture. As a result of these tests, 17 of the 19 viruses could be readily classified as of standard human type—that is, the original material produced typical tuberculosis in guinea-pigs and the culture proved of low virulence for the rabbit.

With the other two viruses (Nos. 128 and 129) the results of similar tests were inconclusive. The original material of these viruses produced very slight tuberculosis in guinea-pigs, and a culture of each gave rise in the rabbit to local tuberculosis only. Further experiments were therefore necessary to determine whether or not this limited pathogenic effect was due to attenuation of the viruses. Cultures of the viruses were accordingly tested on the guinea-pig, one of the two animal species which differentiate standard human from attenuated human viruses. The culture from virus 128 was tested twice on guinea-pigs. On one occasion 2 guinea-pigs were inoculated subcutaneously, each with 1 mgm., and both animals died of typical severe general tuberculosis in 96 and 108 days respectively. The second test was made on three guinea-pigs, one being inoculated intraperitoneally, the other two subcutaneously, each with 1 mgm. The former guinea-pig died in 18 days of tuberculosis, not very severe, and hemorrhagic pleural effusion. One of the subcutaneously inoculated guinea-pigs died in 50 days of general tuberculosis of mild type. The third guinea-pig was killed 228 days after inoculation, and showed tuberculosis limited to the site of inoculation and near the glands. The results in guinea-pigs with this virus are confusing and difficult to interpret. But in view of the fact that 4 of the 5 guinea-pigs inoculated with culture of this virus died of tuberculosis, the disease in 2 being typical and of maximum severity, the slight effect in the fifth guinea-pig should, I think, be regarded as due to some accidental circumstance. I have therefore classified the virus with standard human viruses. The culture of the other virus (No. 129) did not produce typically severe tuberculosis in any of the guinea-pigs inoculated and for this reason I have included it among the atypical viruses. Thus, of 19 eugonic viruses, 18 are classified as standard human viruses and 1 as atypical.

The results obtained in rabbits by the inoculation of the 18 standard viruses are summarised as follows:—

The (young serum) cultures of the viruses were injected subcutaneously into 27 rabbits, the doses ranging from 10 to 60 mgm. One rabbit died prematurely in 30 days and showed very slight disseminated tuberculosis. Of the remaining 26, 2 died 68 and 86 days after inoculation from causes other than tuberculosis and 24 were killed in periods varying from 98 to 150 days. In 2 of these 26 rabbits the disease was confined to the site of inoculation, and in 2 others there was extension to the nearest glands. In the other 22 rabbits there was besides a local lesion and (in 8) disease of adjacent glands some amount of disseminated tuberculosis. The lungs were affected in every one of these rabbits, the disease being slight in 20 and of moderate severity in 2. The kidneys of 4 rabbits contained a minute tubercle or two. A popliteal gland of one rabbit contained a caseous tubercle from which a eugonic culture was isolated, and the omentum of another contained several gritty tubercles.

From one of the 18 viruses (No. 124), in addition to the strain isolated from tuberculous cervical glands, a culture of tubercle bacilli was obtained from another tuberculous focus, an intermuscular abscess. This latter strain, while identical with the cervical gland strain in cultural characteristics, differed from it and other standard human strains in virulence. Details of the experiments with this strain are given in the next section.

### (3) Atypical Strains.

In my first series of cases of glandular tuberculosis all the cultures isolated could be readily classified either as standard human tubercle bacilli or as standard bovine tubercle bacilli. In the present series, on the other hand, three cases have yielded cultures which do not correspond exactly either to the human or to the bovine type of tubercle bacillus. Two of these three atypical cultures were obtained from cervical glands, while the third, referred to above, was derived from an intermuscular abscess in a patient also suffering from tuberculosis of the cervical glands.

A detailed account of the experimental results with each of the three strains follows.

CASE 129.—Female, aged 51 years, with recurrent tuberculous cervical glands. The woman had had glands removed from the neck several times during the last 20 years. The glands sent for investigation were from the submaxillary
